The Supreme Court of Washington, in affirming a judgment of conviction of the defendant of the crime of issuing a prescription for intoxicating liquor after he had been twice convicted of unlawfully issuing such prescriptions, holds constitutional Section 8 of initiative measure No. 3, Laws of 1915, which, among other things, provides that it shall be unlawful for a physician, after he has been convicted a second time of a violation of the provisions of the act, thereafter to write any prescription for the furnishing, delivery or sale of intoxicating liquor. The defendant contended that the legislative power of the state, whether by initiative measure or an act passed by the legislature, could not deprive a regularly licensed physician of the right or privilege of prescribing intoxicating liquor as a medicine, if he believed the patient's condition required it, though it was admitted that for such offenses as that with which the defendant was here charged it would have been proper to deprive him of the right to practice medicine entirely. But the court says that no constitutional provision was called to its attention which it was contended that the law here assailed violated, and no authority was presented holding that the court may declare a legislative act invalid when it does not offend against some constitutional provision. The limitations on the legislative power must be found, if at all, in constitutional enactments, and not in the judgment or discretion of the courts. The law complained of was a valid exercise of legislative power. Nor was there any merit in the contention that, since the statute made it unlawful for a physician to issue a prescription for intoxicating liquor after having been twice convicted of unlawfully issuing such prescriptions, it was error to permit proof of more than that number. The state was not required to cease the introduction of proof when it had offered sufficient evidence to carry the case to the jury and sustain a conviction.

Excluding Children from School for Trachoma

(*Martin v. Craig et al.* (N. D.), 173 N. W. R. 787)

The Supreme Court of North Dakota, in affirming an order of the district court of La Moure County, quashing an alternative writ of mandamus that was issued on the petition of the plaintiff for a peremptory writ to compel the defendants to admit to school certain children, says that the defendants justified their refusal on the ground that one of the children had been found by a reputable physician and by a qualified representative of the federal health service to be afflicted with trachoma, and the other to present a case in which trachoma was suspected. It appeared that during the past few years the disease of trachoma had been present in La Moure County. The school nurse directed the attention of the county health authorities to a number of cases in which schoolchildren appeared to be affected with granulations of the eyelids; and, when some of them were examined by the superintendent of the county board of health, he diagnosed the cases as trachoma. When examined by other physicians, however, and even by representatives of the state public health laboratory, the finding was negative as to trachoma. In some of the cases that had been pronounced trachoma by the superintendent of the county board of health, and not trachoma by the representatives of the public health laboratory, the patients were sent to the government hospital at Pikeville, Ky., for treatment, and the diagnosis was trachoma. There being a number of persons afflicted with this or similar eye trouble, representations were made by the governor of the state to the federal Public Health Service, which resulted in a survey being made by a representative of the latter service, who reported that he found in La Moure County 120 positive and 350 suspicious cases of trachoma. As a result of this survey, a government hospital was established at La Moure, in which patients afflicted might be given the advantage of scientific treatment without charge. Moreover, to prevent the spread of the disease and to secure proper treatment for those affected, the county board of health promulgated an order forbidding admission to school of children who, on examination, were found to be or were suspected of being afflicted, unless they were at the time under treatment for the disease.

In this case the plaintiff produced two physicians who presented what are generally considered to be first-class professional credentials qualifying them to give expert testimony. They had also had ample opportunity to examine the patients and to diagnose the cases. In fact, the children had been patients of one of the physicians. These physicians testified that the children were not afflicted with trachoma, but with folliculosis. One of them also testified that it was injurious to the eye to treat it for trachoma when trachoma was not present; but a careful reading of his testimony disclosed that the injury resulted from a species of treatment that was likely to be resorted to only when the disease was clearly present and when the necessity for radical treatment was indicated. When qualified physicians disagree on the diagnosis of a diseased condition of particular persons, the health authorities and a school board, whose duty it is to execute the orders of the board of health, are justified in acting on the opinion of their own competent experts.

The order of exclusion in this case could not be said to be unreasonable. It excluded only those whose cases were positive and suspected, who were, not at the time under treatment. The seriousness of the disease and its communicable character afforded ample foundation for such an order; and, even conceding that it might be doubted in the present case whether the children in question were affected, the doubt was one that must be resolved in favor of the authorities charged with the serious responsibility of preventing the spread of the disease. This was a case in which mandamus would not issue as a matter of right, but wherein it would issue only in the exercise of a judicial discretion; and this discretion should not be exercised in a way that might result in needlessly exposing healthy children to a disease as serious as trachoma.

Arthritis Deformans in Children.—From a study of cases Byfield concludes that arthritis deformans in children results chiefly from a chronic infection situated in the tonsils and adenoids and in the accessory sinuses of the nose. In children less than 3 years of age, the portal of infection seems to be limited to the tonsils and adenoids. After this time removal of tonsils and adenoids is ineffective in arresting the progress of the disease. A sinus infection should be suspected as an etiologic factor if, after the tonsils and adenoids are removed, there remains elevation of temperature (even if slight), leukocytosis, poor appetite, together with a slowness of the joints to become less painful and swollen. Relapse and exacerbations are definite indications of the need of nasal treatment. Byfield believes that Poncet's disease is probably no more than arthritis deformans in an individual infected with tuberculosis. Although supportive and orthopedic measures are helpful, surgical treatment of the nasal sinuses is to be regarded as the most important therapeutic measure indicated in arthritis deformans in children. The prognosis in uncomplicated cases is good as far as arrest of the disease is concerned. The deformity and functional disability may persist for a considerable time.

Calcium Metabolism of Infants.—The average absorption of calcium oxid by healthy infants taking modifications of cow's milk was 0.09 gm. per kilogram of body weight. Since the average absorption of calcium oxid by breast fed infants was about 0.06 gm. per kilogram, it may be assumed that 0.06 gm. per kilogram is the minimum normal-absorption by infants taking modifications of cow's milk. The excretion and the absorption of calcium were, in general, dependent on the amount of calcium intake, from 35 to 55 per cent. of the intake being absorbed. The calcium absorption was much lower when diarrhea was present. With an increased excretion of calcium in diarrheal stools, there was a marked decrease in soap excretion. The calcium absorption by rachitic infants was much lower than that by healthy infants. In the few cases in which observations were made on infants recovering from rickets, the calcium absorption was higher than the normal average. These infants had received cod liver oil for a considerable period. The administration of cod liver oil regularly increased the absorption of calcium, unless diarrhea was present.

Protein Sensitization.—Baker's studies show that the incidence of food sensitization of apparently normal children is almost a negligible factor, except in the case of salmon, which reaction in any case cannot be considered as an absolute indication of sensitization. The articles of diet most commonly causing disturbance in children presenting anaphylactic symptoms are: oatmeal, potato, eggs, peas, rice, casein, beef juice and chicken. This does not mean that a child with anaphylactic symptoms is not capable of taking any one or all of these articles of diet. Only a careful examination can

reveal the causative factor. In many instances it is only one food, while it may be several.

Heart Block in Child.—A case is described by Eyster and Middleton of partial auriculoventricular dissociation developing in a child, aged 2 years, apparently associated with an acute nasal and throat infection. This child has been under observation for more than two years. At present the cardiac condition is that of a well compensated mitral lesion, associated with a 2:1 auriculoventricular block, with a ventricular rate between 50 and 60. The child has developed normally, and is at present in apparent good health and is normally active. A search of the literature revealed twenty reported cases of heart block in children. Nearly all of these were definitely or probably of congenital origin or occurred during the course of severe and usually fatal diphtheria. The reported case is regarded as being of particular interest in reference to its probable origin and the relatively mild clinical disturbance produced by the condition.

Acetone Bodies in Infectious Diseases.—Observations were made by Veeder and Johnston on forty-one children with scarlet fever, diphtheria, measles and pneumonia. The findings show that while an increased elimination of acetone bodies may occur in the infectious diseases, this does not always take place; that in the same patient it may occur during one infection and not during a second; that it is not dependent on the severity of the infection or the degree of temperature; and lastly, that the decreased intake of food, so consistently a part of an infectious process, does not explain the causation.

Archives of Neurology and Psychiatry, Chicago

February, 1920, 3, No. 2

- *Diagnosis of Peripheral Nerve Injuries. S. D. Ingham and J. H. Arnett, Philadelphia.—p. 107.
- *Nature of Aurae. L. B. Alford, St. Louis.—p. 124.
- *Histopathology and Histogenesis of Syringomyelia. G. B. Hassin, Chicago.—p. 130.
- *Analysis of Blood of Insane Patients. P. G. Weston, Warren, Pa.—p. 147.
- Splints Used for Peripheral Nerve Cases at U. S. Army General Hospital, No. 11. R. C. Buerki, Boise, Idaho.—p. 151.
- *Case of Meningo-Encephalitis (Lethargic Encephalitis). W. W. Hall and C. M. Smith, Brooklyn.—p. 160.

Diagnosis of Peripheral Nerve Injuries.—The authors discuss at length the factors concerned in the diagnosis of peripheral nerve lesions, the production of compensatory movements, and the lesions of individual nerves considered in reference to compensatory movements and other phenomena. They emphasize the importance of careful observation to avoid errors in diagnosis, especially in the atypical cases, which are the ones that offer the greatest difficulties in neurosurgical diagnosis. The fundamental requisites for accurate diagnosis include a thorough anatomic knowledge, a mastery of the mechanics of joint action and discriminating observation. With the application of these broad principles to neurosurgical diagnosis, the difficulties are minimized and the proper treatment can be instituted.

Nature of Aurae.—Alford attempts to point out anew the analogy between aurae and the hallucinations occurring in connection with sleep, hypnosis, crystal gazing, etc. According to this view, he says, aurae should be regarded not as the result of "discharges" of an epileptic nature in some part of the cortex, but as deficiency reactions, like dreams, occurring when there is a "disturbance of consciousness" of a certain type. Their relation to the loss or disturbance of consciousness in epilepsy and migraine is assumed to be the same as that of dreams to drowsy or sleep states; and their content should be regarded as being determined by the same factors that determine the content of dreams and similar hallucinations. Their relation to structural changes may be the same as that of those hallucinations which develop in connection with disease of the organs of special sense or of the nerves connecting them with the brain.

Pathogenesis of Syringomyelia.—From the study of his own case and of previous contributions to this question, the conclusion is drawn by Hassin that in syringomyelia there are a number of specific pathologic changes which differ

totally from those to be found in any other spinal cord lesion—changes which stamp syringomyelia as a distinct anatomopathologic entity. A very full report is made of the results of the microscopic examination of the spinal cord in the author's case.

Blood of Insane Persons.—The blood of thirty insane patients, selected cases of dementia praecox, epilepsy and manic-depressive insanity, was examined by Weston to determine the chlorin and urea nitrogen content. No deviation from the normal content of total nitrogen, nonprotein nitrogen, uric acid, urea, creatinin, creatin, glucose, chlorin or calcium was found.

Meningo-Encephalitis.—The case reported by Hala and Smith was interesting because it displayed not only the characteristic histopathologic lesions observed in the brain by others, but also on account of the intense purulent meningitis and ependymitis found at necropsy. The fact that an organism was isolated both antemortem and postmortem, which evidently was the etiologic factor concerned, is noteworthy. From the clinical standpoint the case was one of meningo-encephalitis, with lethargy and involvement of the motor fibers of the third, sixth, seventh, tenth and twelfth cranial nerves. The etiologic cause was a gram-negative motile bacillus, unidentified, but probably belonging to some intermediate class of the colon-typhoid-enteritidis group. Pathologically, the lesion demonstrated septic meningo-encephalitis and ependymitis, with punctate hemorrhages and perivascular cell infiltration of the centrum ovale, corpus striatum and optic thalamus.

Morphologic Changes During Growth of Bacteria. P. F. Clark and W. H. Ruehl, Madison, Wis.—p. 615.

So-Called Reduced Oxygen Tension for Growing Meningococcus.—Experiments were made by Kohman to determine the rôle that carbon dioxide plays in the cultivation of the meningococcus. He found that by making defibrinated human blood agar medium with a p_{H} of from 7.8 to 8.0, and incubating the meningococcus in a partial atmosphere of carbon dioxide, the same medium may be used for this organism which is used for the pneumococcus and the streptococcus.

Culture Medium for Maintenance of Stock Culture of Bacteria.—A medium of the following composition Worth found favorable for the preservation of *B. typhosus*, *B. paratyphosus*, *B. coli*, *B. dysenteriae*, *B. pertussis*, *Micrococcus catarrhalis*, a streptococcus, and the meningococcus and gonococcus for several months without transfer: Nutrient gelatin: chopped beef, 500 gm.; water, 1,000 c.c. Heated in a water bath (50-55 C.) for one hour. Strain through a bag cloth, the volume being restored: peptone, 10 gm.; sodium chlorid, 5 gm.; gelatin, 100 gm. Dissolve, filter, adjust to 1 per cent. acid. Sterilize for twenty minutes at 100 C. Inoculation is made and the cultures are placed at 37 C. for twenty-four hours after which they are stored at 20 C. with the exception of the meningococcus and gonococcus which are kept at 37 C. Without further attention *B. typhosus* retains its viability, characteristic appearance, and agglutinating power for eight months; *B. coli* for eleven months; meningococcus for eight months; *B. paratyphosus*, *B. pertussis* and *B. dysenteriae* for eight months. The streptococcus was still in good condition at the end of four months.

*Influence of Brilliant Green on Diphtheria Bacillus. J. A. Kolmer, S. S. Woody and E. M. Yagle, Philadelphia.—p. 179.

Varieties of Streptococci and Constancy.—The work reported by Clawson deals with the characteristics of strains of streptococci isolated from various sources. Particular attention is given to the constancy of the special characteristics of streptococci, such as peculiarities in morphology, the action on the blood-agar plate, the fermentation of the various carbohydrates, and the immune reactions, such as agglutination and complement fixation.

Human Fecal Streptococci.—Mannite fermenting nonhemolytic streptococci, according to Oppenheim, are the characteristic predominant types found in the feces of normal individuals. The "indifferent" variety of streptococcus in the feces of normal persons is inconstant in its indifference to the formation of green; green formation would seem to be favorably influenced by the alkalinity of the medium. Hemolytic streptococci are but exceptional findings in the stools of normal, healthy people, and are inconstant in occurrence. No apparent morphologic characteristics, aside from those dependent on rapid, luxurious growth, characterize the human fecal streptococci.

Potency of Concentrated Antitoxic Serum.—The experiments reported by Hixson were designed to investigate the influence of heat on the antitoxic content of the globulin fraction.

Final Hydrogen-Ion Concentration in Bacterial Cultures.—Jones' results show that, to obtain any accurate information regarding the final hydrogen-ion concentration of an organism, a number of factors should be taken into consideration. This characteristic, the limiting hydrogen-ion concentration of a given organism, to have any significance or subsequent application should be defined in terms of the composition of the medium, the initial reaction and any other conditions which favor or hinder abundant growth of that organism.

Streptococcus Hemolyticus in Digestive Canal.—Examination of the gastro-intestinal canal at various levels in rabbits fed hemolytic streptococci showed that this organism does not develop appreciably in the intestine, nor does it readily gain a permanent foothold there. Rabbits with generalized streptococcus infection in joints, blood, etc., showed no

hemolytic streptococci in the intestinal contents. Gastric juice of normal acidity from man and from rabbits kills these hemolytic micro-organisms in from two to five minutes. Gastric juice in achylia may not kill them in several hours. In normal human feces hemolytic streptococci were not found by Davis in fifty-three cases. Hemolytic streptococci when mixed with normal feces will live in the icebox for at least several days. In the incubator they tend to die out rapidly.

Effect of Brilliant Green on Diphtheria Bacillus.—Brilliant green was found highly bactericidal and antiseptic for a virulent diphtheria bacillus in vitro by Kolmer and his associates; the presence of blood and serum in the medium reduced the bactericidal activity. The dye was found also highly bactericidal and antiseptic for staphylococci. Brilliant green possesses much less bactericidal and antiseptic activity for *B. typhosus* and *B. coli*, particularly for the former. The use of brilliant green in the treatment of carriers of diphtheria and pseudodiphtheria bacilli usually resulted in the temporary disappearance of these bacilli from the nose, throat and ears of the treated persons; permanent ridding of these tissues of the bacilli, however, was not observed. Owing to the high bactericidal activity of brilliant green for *B. diphtheriae* and such pathogenic cocci as staphylococci, streptococci and pneumococci, the authors suggest the probability that the clinical use of a 1:250 solution of the drug in water may prove of value in the local treatment of infections caused by these organisms.

Reflex Phenomena in Influenza Cases.—The two chief characters which Ginsburg observed in his cases were: 1. The almost constant presence of pleuropulmonary involvement in every case of pandemic influenza, no matter how mild the clinical course of the disease. 2. The almost invariable accompaniment of reflex phenomena in the neck, chest, abdomen, or back, whenever pleuropulmonary involvement was found on physical examination, at some time during the course of the disease. Ginsburg says, that it was striking to find patient after patient, on the first day of the disease, complaining of reflex pain with no lung signs, and then later to develop pleuropulmonary signs in accordance with the reflex phenomena. Frequently, on further investigation of the case, he was able to find the proof that a diseased viscus was responsible for the visceromotor and viscerosensory phenomena.

Primary Carcinoma of Nasopharynx.—A woman, aged 31 years, had had trouble with her nose for about one year when Smith saw her. Anterior rhinoscopy was practically negative. Posterior rhinoscopy revealed a mass in the vault of the pharynx resembling to some extent adenoids, but seemed too firm for adenoids, was irregular and presented a fungous arrangement. This mass occupied almost the entire vault so that the obstruction to breathing through the

nose was quite complete. Glandular enlargements to the size of hazelnuts were noticeable along the sternocleidomastoid muscle on both sides of the neck. Blood examination revealed a leukocytosis of 12,000; hemoglobin 70 per cent. Blood Wassermann was negative, urine normal. The mass was removed and it proved to be a carcinoma. A large swelling developed under the angle of the right jaw. The glands extending down the right side of the neck to the clavicle were immensely enlarged, attaining the size of a small coconut and other masses of enlarged glands developed, some of them on the lower extremities. The masses on the neck and limb broke down and a septic condition developed with chills and fever. Nausea and vomiting began soon and continued until her death, seven months after operation.

Traumatic Hysteria. M. Osnato, New York.—p. 341.
*Cerebral Glioma and Acute Hemorrhagic Encephalomyelitis. H. S. Howe, New York.—p. 349.

Aneurysm of Right Vertebral Artery.—Analysis of his findings leads Howe to conclude that the diagnosis of intracranial aneurysm in his case was reasonably certain on consideration of the clinical history and the neurologic findings. The history was that of irritation and later paralysis of the right seventh, eighth, tenth, eleventh and twelfth nerves. These lesions could be produced by a new growth, a basilar meningitis or an aneurysm of the vertebral arteries, but it is not probable that a new growth in this locality of four years' duration could produce this group of findings without also causing compression of the medulla or cerebellum and signs of increased intracranial pressure. Basilar meningitis was excluded by the negative serologic findings. A murmur was heard, and while murmur alone is not pathognomonic of aneurysm, in conjunction with other findings it does indicate aneurysm, and in this case it lead Howe to make a diagnosis of aneurysm of the right vertebral artery originating at the junction of this vessel with its largest branch, the posterior inferior cerebellar.

Chronic Nondegenerative Hereditary Chorea.—Wechsler reports the case of a young woman, aged 36, who had been suffering from a chronic nonprogressive chorea for sixteen years. Her father undoubtedly had chorea for twenty years, but, apparently, it was not degenerative in character. One brother had "shakings" of the arms; one daughter was "nervous"; two boys had chorea, one of them a severe form which had lasted almost three years with some mild remission, the other a continuous mild form, also of three years' duration. The clinical picture of the patient herself was typically huntingtonian in behavior. There was no doubt about the hereditary nature of the condition, three generations showing chorea of a continuous and prolonged nature. But, the patient did not show two of the most prominent symptoms which go with a Huntington's chorea. The patient's condition is not progressive, in fact, it is stationary, if not somewhat better; she has no defective mentality, not to speak of even an approach to dementia. Her attention alone is defective. She has attacks of fainting or so-called spells of weakness, which speak in its favor, but there is nothing else, either of psychic or somatic nature, to confirm that diagnosis; nor would a hysterical condition be compatible with chorea. Chorea gravidarum is a remote possibility in this case as the condition began ostensibly with a miscarriage, but that type of chorea usually stops with the emptying of the uterus and only rarely becomes chronic. Also it is never hereditary. Senile chorea is out of the question. Paramyoclonus multiplex is ruled out because of the absence of the lightning-like rapidity and universality of contraction found in this disease, and the bizarre character of gait, facial and tongue movements, and the hereditary or familial attributes are lacking.

Cerebral Glioma and Encephalomyelitis.—The antemortem diagnosis of epidemic encephalitis made by Howe was not

confirmed at the necropsy. A glioma of the right cerebral hemisphere and a hemorrhagic encephalomyelitis were found. The existence of the glioma, although it was of large size, had never been suspected as it had caused neither general symptoms nor focal signs.

Ligation of Internal Iliac Artery in Gynecologic Operations.—According to Massart, ligation of the internal iliac artery, in extensive abdominal hysterectomy for cancer of the neck of the uterus, is at times indispensable; at least, it is to be advised in the majority of cases. This ligation affects all of the territory irrigated by the branches of the internal iliac artery, including the uterine artery. It prevents oozing in the vaginal section, facilitates the maneuvers of liberating the ureters, and relieves the surgeon from caring for a long and minute hemorrhage. Massart practices Faure's ligation of this vessel.

Surgical Treatment of Trifacial Neuralgia.—After dividing the posterior root in sixty-seven cases of trifacial neuralgia during the last two and one-half years, Adson is convinced that patients can be relieved of this disease by this procedure without any serious complications, and he strongly advocates that patients be encouraged to have the radical operation performed in preference to the alcohol injection or avulsion of the peripheral branches, unless there is some doubt concerning the diagnosis, or if the patient is a poor operative risk, or requires preliminary preparation.

Plastic Surgery of Facial Burns.—The result of various plastic methods employed by Gillies for the relief of the distressing deformities and disabilities arising as the result of contractions following severe facial burns are described in detail in connection with case reports.

Postoperative Tetanus.—In the case cited by Huggins, one of complete removal of the uterus and appendages the patient developed symptoms which were typical of tetanus but bacteriologic proof could not be obtained. Smears and cultures were made from the abdominal wound which had healed without any evidence of infection. Cultures were also made from the vagina. No growth could be obtained which in any way resembled the tetanus bacillus. This was true also of the catgut used at operation. A study of the spinal fluid was also negative. The case suggests the possibility of false tetanus under certain circumstances.

Operation for Cancer of Tongue.—The operation described by Blair is said to be properly applicable to the more advanced cases, especially those that also involve the jaw, the floor of the mouth or the base of the tongue, or those with palpable involvement of the submaxillary nodes, and to early cases in which, after removal by a less radical procedure, examination reveals a high grade malignancy. It consists in the block removal from below of the tongue, the structures in the floor of the mouth, all muscles above the body of the hyoid bone and stylohyoid muscles, the submaxillary and submental lymph nodes and as much of the

faucial pillars and pharynx as desired, together with thorough cauterization of the mandible wherever the ulcer approaches or involves it. The mandible is not divided.

Extrapleural Thoracoplasty in Pulmonary Tuberculosis.—Meyer discusses his experience with extrapleural thoracoplasty in suitable patients with advanced tuberculous affection of the lung, in whom therapeutic pneumothorax is not feasible.

Rapid Expulsion of Placenta.—The injection of salt solution into the placenta through the omphalic veins in the cord was tried in thirty hospital cases at the suggestion of Sklavounos. The placenta was expelled spontaneously within from three to five minutes, and without any other manipulation. In a few instances the injection was not entirely successful and the Credé method had also to be used. The failures were due to imperfections in technic. The method is said to be superior to the Credé method and to manual removal. The necessary instruments are: (1) an ordinary syringe; (2) a metallic cannula attached to the distal end of the rubber tube (this cannula must have a perimeter of 1.5 cm. and a groove behind the lumen to prevent slipping of the cord when attached to the cannula); (3) a pair of scissors and a clamp. Fifteen or 20 gm. of salt are added to 1,500 c.c. of sterilized hot water (temperature 50 to 60 C.). The cannula is inserted in the immobilized lumen of the vein and the vein is tied about the groove in the cannula. The salt solution is injected into the vein which swells and takes on a white instead of the previous blue color. The swelling of the arteries proves that the injection has been successful. So soon as 200 c.c. of the salt solution is injected, detachment of the placenta begins. When water comes from the arteries, they are pressed with a clamp and the result of the injection is waited for. To prevent formation of clots in the vessels and facilitate the circulation of the injected liquid, Sklavounos adds 2 per cent. sodium nitrate to the salt solution.

Safety Factors in Surgery.—Frank's observations lead him to conclude that a patient is not in the best possible condition to undergo any surgical procedure when he has a hydrogen-ion concentration of his blood below p_{H} 7.35; a carbon-dioxid tension in the alveolar air below 35; a soda tolerance test above 15; an Ambard coefficient above 0.10; a urine which shows but little variance in quantity from day to day and with the specific gravity varying less than seven points, regardless of the intake; also nocturnal polyuria; a phenol-sulphonphthalein output below 40, unless it can be accounted for by disease of other organs, the liver particularly.

Bilocular Stomach.—Pauchet has operated in twenty-five cases of bilocular stomach, a resection being done in twenty-three cases. These operations were divided as follows: one gastropasty; two gastrogastrotomies; either alone or associated with a gastro-enterostomy; four mediogastric resections, and eighteen pylorogastrectomies. He has reoperated on two patients on whom a pyloroplasty, gastrogastrotomy and gastro-enterostomy had been performed. These operations resulted in two deaths; one case was complicated by a perigastric abscess and in the other there was an extensive perforating ulcer. These operations were performed under regional or spinal anesthesia with or without several whiffs of nitrous oxid for several seconds. Pauchet says that the extensive resections have given by far the best end-results.

Tenia Solium in Spinal Cord.—Kimpton is of the opinion that his case is the first in this country and the only case where a pork tapeworm has been removed successfully from the spinal cord during life. Mercur found a similar tumor of the spinal cord, but at necropsy. A diagnosis of spinal cord tumor at the fourth or fifth dorsal segment had been made in Kimpton's case and operation was advised. A laminectomy was done on the fourth, fifth and sixth dorsal vertebrae and the cord exposed. There was a distinct difference in the tension of the cord. The tension appeared to be greater, and the cord was paler in this region. The cord membranes were incised and this revealed a translucent tumor. The tumor was easily shelled from the cord. It appeared as a gelatinous mass. The pathologic diagnosis was cysticercus racemosus.

Epididymectomy.—Stern separates the epididymis from the blood supply of the testis by careful dissection and then ligates the epididymis.

Rammstedt Operation on Adult.—Graham reports a case of pylorospasm in a man, aged 46. Operation produced a cure.

Beef Bone Splints.—Brenizer discusses the use of beef bone splints and cylinders which have been boiled and kept in alcohol until every organic living cell is dead.

Surgical Treatment of Intestinal Stasis.—Horsley reports the end-results in seventy-four cases of intestinal stasis in which he operated between February, 1912, and September, 1917. In twenty-two patients the operation performed was appendectomy and division of Lane's band. Thirteen of these reported that they were greatly improved, eight that they were improved. There was none unimproved and no deaths. One patient did not report. In twenty-seven cases, the Coffey, or hammock operation, which consists in suturing the gastrocolic omentum to the abdominal wall, was done. Of this number, twelve reported great improvement, ten were improved, and two were unimproved. Two died, and from one patient no report could be obtained. In seventeen patients cecostigmoidostomy was done. In this group six patients were greatly improved, four were improved, five were unimproved, one patient died and from one patient no report was obtained. In five cases the Coffey operation and cecostigmoidostomy was done. Of these patients three were greatly improved and two were unimproved. In three cases ileostigmoidostomy was done. None of these patients was greatly improved, but two are classed as improved. All recovered from the operation. One patient died from pneumonia two years and two months after leaving the hospital. Summing up this group of seventy-four cases, thirty-four patients (46 per cent.) are greatly improved; twenty-four (32.5 per cent.) are improved, nine (12 per cent.) are unimproved, four (5.5 per cent.) are dead, and three (4 per cent.) were not heard from. The reports from these patients varied

from five months to five and one-quarters years from the time of operation.

Home Treatment of Pulmonary Tuberculosis.—This paper was abstracted in *THE JOURNAL*, Nov. 29, 1919, p. 1722.

Controlling Secondary Hemorrhage After Operation for Piles.—In a case cited by James secondary hemorrhage was controlled without disturbing the patient, by slipping a rubber glove finger over a glass tube, 3 inches long, and wrapping the open end of the glove finger securely around the near end of the tube, and attaching to the projecting tube a rubber bulb such as is used in a common atomizer. By inserting this rubber covered tube between the sphincters and pumping in air, sufficient compression was produced to control the hemorrhage, with no pain or distress to the patient and without disturbing him in the least. A clamp was placed on the rubber tubing, and the apparatus was left in place for three days, when on removing the clamp the air escaped and in an hour or two the apparatus had come away without the knowledge of the patient.

- *War Neurasthenia—Acute and Chronic. D. W. Carmalt Jones.—p. 171.
*Hyperglycemia in Mental Disorders. F. H. Kooy.—p. 214.

War Neurasthenia.—After having cases of this type under observation for one year, Jones is convinced of the reality, the severity and the amenability to treatment of this disease. He believes that the symptoms of this condition are due, in part at least, to prolonged overstimulation of the ductless glands, chiefly the suprarenal. Jones pleads for recognition of this disease and its appropriate treatment by competent men, if possible in a special hospital given over entirely to these cases.

Hyperglycemia in Mental Disorders.—Two of ten cases of dementia praecox examined by Kooy with reference to the blood sugar content showed a higher count than 1.30 per mille after breakfast. In nine cases of dementia paralytica, the average of the highest amounts was 1.33 per mille. Six of the nine patients had, without excitement or apoplexy, an amount above 1.30 per mille after breakfast. An examination of nineteen cases of melancholia showed that in this disease the blood sugar is much increased. If 1.10 before breakfast is the normal limit, then nine patients had surpassed that figure. Examination of four cases of true neurasthenia and psychasthenia, without any bodily abnormalities, showed plainly that emotions cause hyperglycemia in man. The blood sugar is very much increased when the patients who have confusional insanity are in a highly emotional state, whereas it decreases on recovery. The results with mania are extremely variable. Optimism and highly increased blood sugar run parallel. Increase in blood sugar, as a rule, is highest in real emotional states, such as may occur in mania at its climax; it is smaller,

although still present, in the milder form of mania, and absent in those hypomaniacal forms in which the patient is only optimistic, cheerful and inclined to be jocular. Emotions, especially those of a depressive character, cause an increase in blood sugar. They, therefore, have a deteriorating influence on diabetes mellitus. They may cause a temporary hyperglycemia and even glycosuria in normal persons not suffering from saccharin diabetes. Even a considerable increase in blood sugar need not be a symptom of disordered metabolism. Hyperglycemia may occur with any emotional state in mental disorders. Kooy found it to occur in emotional states of patients suffering from general paresis, epilepsy, dementia praecox, traumatic neurosis and neurasthenia. Glycosuria and hyperglycemia are most frequent in melancholia. Kooy's investigation has shown that hyperglycemia before breakfast (spontaneous hyperglycemia) is not a constant symptom in melancholia, but it was constantly present after the patients had taken ± 200 c.c. of milk and ± 100 gm. of bread and butter (alimentary hyperglycemia). With marked anxiety there was the highest amount of sugar in the blood.

Surgery of Heart.—In certain cases of purulent infection of the pericardium, Ballance holds that the culdesac of Haller should be drained. He believes that the operation is justified on anatomic and pathologic considerations. He feels that the surgery of the heart will occupy in the coming time a conspicuous place in surgical practice. The reward of success will attend efforts in so far as the heart is treated as one of the ordinary tissues of the body and the method of operation conforms to the fundamental principles of surgery.

Significance of Tachycardia.—According to Wilson, tachycardia in a man who is up and about is compensatory in character, the addition of acceleration to augmentation. It points to the presence of a mild infection, and can be removed only by removing the infection. There is evidence that the action of the toxin is directly on the cardiac vagus.

Ureter Calculus of Unusual Size.—The stone in Kidd's case measured $2\frac{1}{4}$ inches in its long diameter and 1 inch in its short diameter, and weighed 1 ounce. It consisted of phosphates, with a trace of oxalates, and contained no cystin, no carbonate and no uric acid. The stone lay below the pelvic brim. Very few symptoms had been caused by it.

Acute Hydropneumothorax.—In Thomas' case the acute hydropneumothorax resulted from an old gunshot wound of the chest. The patient recovered in spite of a communication between the pneumothorax and the stomach.

Carbon Monoxid Poisoning in Mines.—Carbon monoxid is produced during explosion of charges in mines. Where the mine is deeply placed, or where a small charge has been used so that the surface of the ground has not been broken, the gas is either forced into the underground system of mine galleries or gradually percolates into the galleries through cracks and porosities in the ground and in these circumstances the miners become subject to this form of gas poisoning, the severity of which may range from mere headache and debility to coma and death. In some cases the reflux of carbon monoxid after an explosion has come up to the mine shaft and caused gas poisoning in the trench in the near vicinity to the mine entrance. Carbon monoxid has the effects of a cumulative poison, even in relatively small quantities. The various explosive substances (with certain exceptions, such as the acetylene compounds) contain within themselves a considerable amount of oxygen, which is, however, generally insufficient for the complete oxidation of all the constituent oxidizable elements. In consequence, not only may there be the formation of carbon monoxid, but hydrogen, marsh gas and certain other oxidizable substances may be liberated as the result of the detonation of various explosives. The methane is said to result from interaction of the hydrogen with the oxids of carbon as the hot gases cool down and not to be formed at the time of the explosion. Nitroglycerin is an example of the explosives which are completely oxidized on detonation, and this substance exists to the extent of 75 per cent. in dynamite and 30 per cent. in cordite, besides being present in smaller proportions in many of the blasting gelatins. Carbon monoxid is produced as the result of the use of a large series of explosives, such as gunpowder (whether in the form of rifle powder, "cocoa powder," or blasting powder), gun cotton (either by itself, or as cordite, of which it forms 65 per cent.; smokeless powder, which is 98 per cent. gun cotton with 1 per cent. of acetone and 1 per cent. of moisture, etc.; or the blasting gelatins), and ammonal, the latter of which is used extensively and in enormous quantities. The fulminate in the detonators also liberates carbon monoxid in small amount. It is the carbon monoxid thus produced, and produced in these high proportions and enormous quantities, which is absorbed in the chalk and forced into the fissures, either existing naturally or resulting from the explosion of the charges that have been laid, that is being constantly encountered by those engaged in the work of the various tunneling companies, and which frequently results in the occurrence of cases of gas poisoning of this specialized nature. Owing to the gas being contained in cracks among the chalk it is found in what are described by the miners as "pockets" and owing to this fact in many instances the gas is liberated too suddenly for the men to notice any alteration in the behavior of the test animals (mice or canaries) that they have with them before they are themselves beginning to be affected.

Rickets in Germany: Effects of War on Children.—Engel says that only in the very latest period of the war did weakly children under weight begin to appear in greater number. The average of weight of new-born children, as observed in the lying-in hospital, was then reduced. The general health of infants was good, the mortality rate low. The number of births had fallen sharply, a circumstance which always reacts favorably on infant mortality. In addition to this, chiefly in consequence of the shortage of cow's milk, and encouraged by a special grant from the state, breast feeding became more prevalent. The mortality rate of infants was permanently reduced. The position of children between two and five years of age, however, became more and more unfavorable. In spite of the fact that their number also fell, and, therefore, other things being equal, their prospect of life became better, the mortality rate did not fall, but from 1915 on practically reached the infantile mortality rate and even exceeded that of 1918. In normal times the mortality of the children from 2 to 5 years old was not half as great as that of infants. When the statistics are examined, it is seen that the increased number of deaths are not referred to the infectious complaints, but to inflammation of the lungs, but in reality the increase of deaths of rachitic children was the result of respiratory insufficiency,

or "inflammation of the lung," and which makes it probable that the high mortality of little children is really to be ascribed to rickets.

Schick Reaction for Determination of Susceptibility to Diphtheria.—In Leete's experience the Schick test appears to be of definite value in detecting diphtheria susceptibles, and as such has many possible applications. It is easy to perform and free from any danger. A reliable toxin and careful technic are essential. Once the difference between a positive and a pseudoreaction are appreciated, reading is easy, but if there is any doubt, controls of heated toxin should be used. The best times for reading are twenty-four hours, three days, and ten days after the test.

Bacteriology of Influenzal Pneumonia. A. H. Tabbutt.—p. 499.

*Case for Diagnosis (Thomsen's Disease?). A. W. Campbell.—p. 506.

Thomsen's Disease?—Campbell reports the case of a man, aged 27 years, who for ten or eleven years had shown apparently remarkable muscular development, but whose real muscular power was slight and subject to easy fatigue, whose every movement was hampered and impeded by "intention rigidity" and tendency to tonic contraction, and whose muscles were unduly firm in relaxation and show an alteration of electrical excitability, suggesting the myotonic reaction. In these respects the clinical picture fitted Thomsen's disease. It was incomplete, however, inasmuch as the marks of familial and congenital origin were wanting.

*Mucor Isolated from Feces of Beriberi Patients. S. Kiyosaki.—p. 1.
*Quantity of Diastase in Normal Urine. E. Saigusa.—p. 1.

Mucor Isolated from Feces of Beriberi Patients.—Kiyosaki examined the feces of thirty beriberi patients. In ten instances he found the identical mucor. Injected into frogs, pigeons, guinea-pigs and rats, it caused toxic effects, producing, especially in frogs, symptoms resembling motor paralysis.

Quantity of Diastase in Normal Urine.—The urine of 114 persons was examined by Saigusa by the one-half hour method of Noguchi and Wohlgemuth. The quantity of diastase thus determined varied from 8 to 64, in the majority of cases ranging from 16 to 32. It had, to a certain extent, a relation to the specific gravity of the urine. The starch paste used by Saigusa in his experiments was prepared from official potato starch by heating it for a certain time to destroy amylopectin contained in it, and then passing it

through a filter. The author claims that this starch paste could well take the part played by the soluble starch of Kahlbaum in this experiment.

Cardio-inhibitory Action of Magnesium Chlorid on Turtles. K. Tsugane.—p. 39.
Infantile Scarlet Fever. T. Nomura.—p. 40.

Effect of Calcium, Potassium Chlorid and Magnesium Chlorid on Respiratory Center.—Perfusing the respiratory center of a turtle with a mixture of sodium and calcium, or sodium and potassium salts, and also magnesium, only showed that the effective action of the respiratory center was greatly increased, but if a physiologic quantity of potassium salts was added to an isotonic sodium chlorid solution and this mixture was perfused, examination of the respiratory center did not reveal an increased effectiveness. In thirteen cases comparison was made with the 0.7 per cent. magnesium chlorid solution. There was immediately quickening of rhythm in the heart, but the same experiments showed that the application of magnesium chlorid solution to the respiratory center causes immediately abolition of the functions of the medullary center.

Meningococcemia Without Meningeal Symptoms.—Ribierre and his co-workers state that they have recently encountered several cases of prolonged intermittent fever for which the meningococcus was responsible. Five complete case reports are given and two others without bacteriologic control. The chills and fever are of the malarial type, eruptions are constant, as also pains in muscles and joints during the febrile periods, frequently accompanied by redness and swelling around the joints. In nearly every case the cocci finally invade the meninges, the tardy meningitis in some cases first giving the clue to the nature of the disease. In three of the cases reported the interval was one, two and three months from the first symptoms, but intraspinal serotherapy then proved promptly effectual and cured at the same time the general infection. Lumbar puncture long before had yielded a limpid and sterile fluid, but it contained 0.3 or 0.4 per cent. albumin with moderate leukocytosis and abnormally large proportions of polynuclears. The fluid was also of this type in another case in which the meninges seemed to escape entirely, although the febrile meningococcemia persisted for four months. The cocci were isolated from the rhinopharynx as well as from the blood, and the onset of the disease was that of frank septicemia. There was no epidemic at the time, the cases occurring between November and April. In one of the two fatal cases there was tardy localization of the meningococci in the endocardium. The eruptions may be purpuric, papulous or nodular. The experiences related emphasize the importance of identifying the exact strain of meningococci involved, and giving this specific serotherapy, using a polyvalent serum until this is possible. In these cases scarcely any benefit was apparent from the antiserum until the strictly specific antiserum was used. They advise five injections at twenty-four hours intervals, alternately subcutaneous and intramuscular; if improvement is not observed in the following days, they give it by the vein, and in case this fails, inject it into the spinal cavity, regardless of whether there are meningeal symptoms or not. The patient should be kept under observation for at least a month after the supposed cure as there may be a tardy relapse. The nasopharynx should be examined for meningococci and, if found, the antiserum in powder form should be insufflated. In one of the cases, treatment was with neo-

arsphenamin by the vein, with recovery after 1.65 gm. had thus been injected in the course of a month. The Wassermann test was negative. No benefit from this drug was apparent, however, in any of the other cases. In rebellious cases others have reported good results with autovaccines and revulsion by a turpentine abscess.

Uremic Meningeal Reactions.—Roger presents evidence to show that the meningeal reactions which develop in the course of uremia do not seem to be directly caused by the retention of nitrogen. They are usually the results of intercurrent cerebral complications, hemorrhage and softening, for which the kidney sclerosis is only indirectly responsible. Cerebral hemorrhage was found by Frerichs in 11 of 292 uremia cadavers, and 3 in 112 by Rosenstein. Canti has recently published 3 cases of cerebral hemorrhage or softening with azotemia of 0.9 to 1.5 gm. per liter. Meningeal hemorrhage is not exceptional with chronic kidney disease. The latter raises the blood pressure until some vessel ruptures. This explanation of the meningeal reactions in uremia as mechanical rather than toxic, would be verified oftener if the cerebrospinal fluid was examined more carefully at necropsies. Slight xanthochromia may escape detection unless the tube is inspected lengthwise, but this proves the presence of blood, thus adding a fourth type to the three biologic types of uremic meningeal reactions, those with hyperalbuminosis, those presenting merely hypercytosis, or both combined. Acute infectious meningitis in a patient with uremia is often mistaken for uremic meningitis. The pneumococcus is usually involved, but syphilis and tuberculosis may likewise be responsible. In one such case, with positive Wassermann reaction, the convulsions subsided after lumbar puncture, but the headache and torpor did not improve until under treatment for syphilis. When the uremia alone can be incriminated for the meningitis or meningeal condition, the spinal fluid may show merely cytologic and chemical reactions, without clinical manifestations, or these reactions may be encountered in the course of neuro-uremia, febrile or not, with headache, vomiting, convulsions, stiffness of the back of the neck, Kernig sign and contracture of the spine. But Roger insists that most of these symptoms are the work of the azotemia rather than any special injury of the meninges. The urea poisons the cortex. He had one case in which extreme retention of sodium chlorid alone, without uremia, was responsible for convulsions, etc. To prove the various points in his article, he cites numerous concrete examples from his own and others' experiences.

Periodic Paralysis.—Guillaumin and Barré report the case of a soldier of 36 who had paralysis of the arms come on nearly every night, about 2. There is no pain and no paresthesia, but the patient is unable to lift even the bed clothes. By 7 or 8 the paralysis passes off, and his muscles keep normal during the day. Only occasionally, when writing, he has to stop as his arms and legs feel heavy, but walking around a bit restores normal conditions. He has noted symptoms of the kind for sixteen years, but the actual paralysis did not develop until in the trenches in 1915. The attacks of paralysis vary widely in intensity, and during the severer ones the electric excitability of the muscles and nerves disappears completely. The muscles innervated by the cranial nerves never showed a trace of paralysis during the several months the man was under observation. The tendon reflexes disappeared during the severer attacks, but the skin reflexes showed no modifications, and there never were any sensory disturbances. There was no history of malaria, and although the Wassermann reaction was positive in the blood on two occasions, they are inclined to doubt its pathogenic importance here. The spinal fluid shows no sign of neurosyphilis, and no benefit was realized with tentative specific treatment, nor from strychnin, epinephrin, camphor, repose, etc. There seems to be some intermittent intoxication, some poisons of unknown origin accumulating during the intervals, and then acting on certain peculiarly susceptible nerves.

Capacity of the Pleural Cavity.—Rist and Strohl comment on the extreme variability of the curves when the quantities

of gas introduced into the pleura for artificial pneumothorax are compared with the corresponding intrapleural pressure as abscissa and ordinate. The variability depends on the elasticity of the lung, permitting the spreading apart of the sheets of the pleura. A sudden drop in the pressure curve is a sign of sudden increase in the capacity of the pleura, entailed by the breaking of adhesions. The pleural cavity is not a space with rigid walls.

*Anatomy of Snapping Hip. A. Mariau.—p. 807.

*By-Effect with Mercuric Cyanid. L. Renard.—p. 808.

French Surgery During the War.—In the course of this opening lecture of the "operations and apparatus course," Duval says of the Carrel method that it represented immense progress at the time of its introduction, restoring confidence when despair at the impotence of surgery was almost universal. But the Carrel method is based on two errors, the assumption that a wound after it has been cleared of devitalized tissues requires disinfection; in reality the sound tissues are perfectly competent to cope with the few microbes left, provided—and this was Carrel's second mistake—that there are no streptococci in the wound. He merely counted the bacteria, paying no heed to the species. It was Henri Gaudier, he says, who blazed the way for the successful treatment of war wounds, proclaiming that all devitalized tissue must be cleared out, but that when this was done, then the wound could be safely sutured. Tissier showed that this was true only in the absence of the streptococcus; by excluding or waiting for the disappearance of the streptococcus, then wounds can be confidently sutured. To France, Duval reiterates, belongs the honor of discovering the importance of the biology of the wound: the toxicity of crushed, devitalized tissues, the excision of all such, and the primary suture at once or a few days later when the wound has been cleared out and absolutely protected against contamination. The French also proclaimed that wounds anywhere in the body, even in the lungs, should all be treated on these same principles.

Illumination and Aspiration During Operations.—Rocher expatiates on the importance of a forehead electric light for all operating on cavities, and the importance of continuous vacuum aspiration during operations with which hemorrhage is liable. He uses for the purpose an electric pump designed for compressing air for therapeutic hot air jets. He holds the aspirating cannula in his left hand, sucking up with it all blood, pus, and other secretions, while the right hand wields the curet or other instrument, or an assistant manages the vacuum aspiration. Several cannulas are kept ready in case one gets blocked. He has found this aspiration cleansing of the wound especially useful in operations on bones, on the face and jaws, and on the throat and palate. A minor advantage of the aspiration is that it materially reduces the number of sponges needed at operations.

Mercuric Cyanid by the Vein.—Renard calls attention to the subjective odor of bitter almonds which is sometimes experienced as mercuric cyanid is given by the vein. He now warns patients to expect it.

*Esthetic Laparotomy Incision. F. Jayle.—p. 1.

*Advantages of Filiform Drainage for Chancroidal Bubo. A. Floquet.—p. 5.

Esthetic Gynecologic Incision.—Jayle expatiates on the advantages of a small transverse incision, to one side of the median line, for access to the adnexa on one side and for removal of the "cold" appendix, under general anesthesia. He gives twenty-four views of the various steps of the operation. It takes a little longer than with a larger incision, and the surgeon has to work with fingers and forceps, and cannot introduce his hand. But the lack of a disfiguring scar and the advantage for the patient of this reduction to the minimum of intraperitoneal manipulations counterbalance

this. He has been able to resect the tube from the other side as well, without enlarging the incision, and even to resect nine tenths of the other ovary.

Veneral Disease in Swiss Army. W. R. Schnyder.—p. 1988. Conc'n.

Precipitation Test for Syphilis.—Galli-Valerio declares that his findings in 241 cases confirmed the great value of Sachs-Georgi precipitation test with cholesterolized organ extracts in the serodiagnosis of syphilis. As the technic is improved, he thinks it will supersede the Wassermann test almost completely as it is so simple and easy. The findings paralleled those of the Wassermann test in 77.59 per cent., and in some of the discordant cases, the effect of treatment had modified the response. The organ extract is made with 100 c.c. of an alcoholic extract of beef heart (1 gm. of heart to 5 c.c. of alcohol); 200 c.c. of alcohol, and 13.5 c.c. of a 1 per cent. alcoholic solution of cholesterol. When ready to use, one part of this extract is mixed with one part of 0.85 per cent. physiologic solution, agitated, and four parts of the latter are added. The serums to be tested should be fresh and clear and should be inactivated by heating for half an hour at 55 or 56 C. To 1 c.c. of the serum to be examined, diluted ten times with the 0.85 per cent. saline, is added 0.5 c.c. of the extract diluted as stated above. The whole is well mixed and incubated at 37 C. for two hours and then kept for twenty, twenty-four, forty-eight hours at room temperature, after which the findings are recorded. Meyer suggests that the interval can be shortened by centrifuging the tubes after three or four hours' incubation. The flocculation and precipitation can be estimated by placing the tubes slanting on the black background of a Leitz dissection microscope, and examining with a No. 8 glass. This renders an agglutinoscope unnecessary.

Volvulus as Complication of Appendicectomy.—Dardel removed the appendix in a girl of 8 with threatening symptoms, but the peritoneum was found intact. The appendicitis was of the so-called catarrhal type. There were no adhesions, but four weeks later the last loop of the ileum became twisted and gangrenous. All the cases on record of post-appendicectomy volvulus with gangrenous loop terminated fatally with one exception besides the case here reported. The diagnosis in this case was unmistakable but the general condition was so good that the child was kept under observation for several hours. The circumstance that in seventeen hours the bowel was found gangrenous and on the point of rupture, emphasizes anew the danger of delay. The case teaches, he says, the inadvisability of removing the appendix for purely prophylactic purposes, and it also teaches that when abdominal disturbance follows appendicectomy, it should not be ascribed as a matter of course to errors in diet. The earlier the diagnosis, the better the outlook for these tardy complications of appendicectomy.

Gap in Transverse Mesocolon.—The retrospective diagnosis was that an old gastric ulcer had in time entailed stenosis of the pylorus and adhesions to the pancreas and the mesocolon. The traction on the latter had caused it to atrophy, and in lifting a basket of washing a sudden violent pain gave notice of a tear in the mesocolon. A loop of intestine slipped at times through the gap, with transient occlusion, but this spontaneously corrected itself several times. The opening was large enough for the circulation in the loop to proceed unhindered for a time. Conditions gradually became aggravated, but after a gastro-enterostomy and suture of the gap in the mesentery the extremely emaciated patient recovered and has called her health perfect during the nine years since.

 *Prosthetic Appliances, Especially for the Arm. A. Serra.—p. 593.

Development of Collateral Circulation.—Bolognesi reviews what has been written on this subject in recent years and the experimental research in Italy by Porta, Talma, Stefani, Orecchia and Fichera since 1845. He then gives the roentgen findings in the circulation in six dogs killed from four to ninety days after ligation of the external iliac artery. The abdominal aorta was injected with a contrast suspension of 60 parts minium in 60 parts liquid petrolatum and 30 parts oil of turpentine. In comparison with the intact side, all the vessels below the ligature were found larger and they had more ramifications. The direct lateral circulation was insignificant and of tardy development, while the indirect lateral circulation developed to a remarkable extent, bridging the gap in the artery. His illustrations show this bundle of bridging vessels, numbering twenty-seven in one of the dogs and a still larger number in another. The ligated artery in one finally regained partial permeability. The entire circulatory tree had increased generally in size below the ligature, ensuring resumption of arterial circulation in an almost perfect manner. Persons with a particularly well developed sciatic artery seem to be more liable to develop satisfactory collateral circulation after ligation of the external iliac, as conditions thus resemble more closely the conditions in the dogs in his experiments.

Hernia of Muscle.—Ferrarini analyzes the extensive international literature on hernia of muscle, and describes his own experimental research on myoele and a personal clinical case in which the tumor in the thigh had been noted for seven years. There had been some pain at first after a sudden muscular strain which had evidently caused the hernia. Later the tumor was tender, but the man paid no attention to it until he noticed that it seemed to be growing larger. An operation was done on the assumption of a lipoma, but the tumor proved to be the belly of the rectus muscle. Some of the fibers had been torn across and had retracted, and a cyst had formed in the gap. The clinical picture therefore of a myoele may differ widely according to the pathologic conditions encountered and the site.

Varus Deformity of the Shoulder.—Angeletti discusses the findings in five clinical cases and some anatomic specimens in which there was deformity of the shoulder corresponding to coxa vara in the hip joint. It was of traumatic, inflammatory or rachitic origin, or occurred in a cretin or from chondrodystrophy. The roentgen findings in his clinical cases are reproduced.

Congenital Dislocation of Hip Joint and Tuberculosis.—Cesarano relates that among the 2,000 cases of congenital luxation of the hip joint at the Rizzoli Institute there were two cases in which the operation for correction of the deformity, or casual trauma, was followed by rapid development of a tuberculous process in the joint, although there had been nothing to suggest tuberculosis in the child before. In one, the deformity was bilateral, but the right joint had required more forcible and repeated correction, and the tuberculous process developed in this joint. The child came from a tuberculous family, but roentgenography had shown apparently normal conditions before the intervention. The process had developed in the older child after a trauma, nine years subsequent to the correction of the deformity. Only a few such instances are on record, he says, and the fact that tuberculous processes only exceptionally follow the stress of correction of congenital luxation of the hip joint,

testifies anew that trauma alone is not able to induce a tuberculous process in a healthy subject. With inherited or acquired taints, even slight trauma, even any transient overuse of the part, or prolonged morbid congestion may be enough to induce the localization of a tuberculous lesion.

Plaster Cast for Immobilization of the Shoulder.—Taddei extols the advantages of the right-angled or square plaster frame which holds the arm on a level with the shoulder, the forearm on the same level or sloping downward. The findings after healing show fine anatomic, functional and radioscopic results. The patients do not object to the square frame after the first.

Artificial Hands and Arms.—Serra discusses what has been done in the line of prosthetic appliances in Italy and elsewhere in the last two or three years, giving forty-three illustrations and the indications for the different types of artificial limbs and working hands.

 *Sterility. A. Brun.—p. 1449.
 Quinin in the Prophylaxis of Malaria. F. Paoletti.—p. 1458.
 Income Limit for State Insurance against Sickness. L. Verney.—p. 1469.

Symptoms of Meningitis.—Fossataro reports the case of a man of 37 who suddenly began to cough and expectorate, with fever, headache and vomiting. Râles were found at the base of the right lung, and the back of the neck was stiff. The meningococci found in the spinal fluid had evidently invaded the lungs and cerebral meninges simultaneously; the course was distinguished by torpor throughout, the man dying the third month. The spinal meninges did not seem to have been affected. The loss of balance and tendency to fall had suggested a tumor in the cerebellum but vision was normal, except for strabismus. The torpor was evidently the result of the hydrocephalus in the ventricles which was also responsible for the lack of control of the sphincters. Necropsy revealed merely purulent leptomeningitis of the lower surface of the cerebellum with hydrocephalus, ventricular and also intermeningeal, at the base of the brain.

Causes of Sterility.—Brun analyzes 300 cases of sterility in women from his practice at Trieste. In 230 cases the women had never conceived; in seventy cases the women had already gone through an abortion or pregnancy. His experience confirms anew the importance of patience and perseverance in measures to correct the congenital or acquired defects impeding conception. The genitals were apparently normal in thirteen of the 230 cases of primary sterility; in 107 there were congenital defects, in 102 inflammatory processes were responsible, and fibroma in eight.

Cinematization of the Jaw.—Avanzi relates that Pellegrini, in discussing motor plastic amputations recently, suggested that it might be possible to form loops in the muscles after amputation of the lower jaw which might serve for vitalization of the prosthesis, as after motor plastic amputations of the leg. Avanzi reviews the various elements that would be

necessary for such intervention, and especially the cooperation of the surgeon and the mechanic or, better yet, the double training in one person.

*Serodiagnosis of Echinococcus Disease. A. Gasbarrini.—p. 441.

*Rhizomelic Spondylosis and Osteomalacia. N. Pende.—p. 446.

*Spontaneous Nystagmus. G. Bilancioni and A. Romagna-Manoia.—p. 461.

Serum Test for Echinococcus Disease.—Gasbarrini applied the test by the intradermal technic and obtained a positive response in all his twelve cases of hydatid cyst, except in one case in which the cyst had suppurated and thus had ceased to be "active." He commends the ease and harmlessness of the test. It is made with serum from bovine hydatid cysts, filtered; after addition of one drop of phenol to 20 c.c. of the fluid it is set on ice. It keeps active for about a month. Giani obtained satisfactory results also with the Abderhalden test applied to human and bovine serum from subjects with echinococcus disease, and it was positive in seven of Gasbarrini's twelve cases. After surgical intervention the intradermal reaction veers to negative.

Rhizomelic Spondylosis and Osteomalacia.—Pende gives an illustrated description of a case of this combination in a woman of 48 who had had several attacks of articular rheumatism in the last eighteen years. Nothing can be found to indicate any special endocrine disturbance. The associated osteomalacia throws light on the etiology of the rhizomelic spondylosis, as it suggests a common origin in a trophoneurosis of bones and joints. It is localized in this case in the inferior cervical and the lumbosacral metameris and the adjoining joints and corresponding joints in the limbs. The prevailing views on spondylosis are analyzed and compared.

Spontaneous Nystagmus.—The present status of our knowledge on this subject is presented by Bilancioni and Manoia who noted spontaneous nystagmus in 150 of 3,000 aviation candidates. There was nothing otherwise to suggest pathologic conditions in the labyrinth, but there were always signs of functional disturbance in the nervous system, exaggerated reflexes, dermatographism, tremor, etc. Many were accepted and passed satisfactorily through the course of training. The details are given of 4 cases of pure spontaneous nystagmus, and of 8 with heart, kidney or nervous disturbances, also in 2 cases after a fall while flying, and in 2 cases in which there was a history of an old healed otitis media. In 3 others the tests revealed abnormally long reaction to visual and auditory stimuli. They take up in turn the various hypotheses advanced to explain nystagmus. Their conclusion is in favor of some causal functional disturbance in the centers which control the movements of the eyes, this disturbance being probably of embryonal origin and located in the center itself or the cortex or connecting nerve fibers, and consisting in the lack of normal balance between the acting and antagonist elements. The nystagmus occurred only when the eyeballs were rotated to the farthest limit.

Crónica Médica, Lima, Peru

September, 1919, **36**, No. 675.

*Treatment of Trigeminal Neuralgia. M. Sixto Chavez.—p. 299.

*The Psychology of Insanity. H. F. Delgado.—p. 316.

*Emergency Splenectomy for Rupture. E. P. Manchego.—p. 327.

Trigeminal Neuralgia.—Chavez reviews the broad field of measures that have been recommended for treatment of trigeminal neuralgia for which no cause can be discovered. In one case he cured supra-orbital neuralgia of three months' standing in a student by application of electricity, but the interval since has not been very long. He cites A. Courcelle's success in treating neuralgia by subcutaneous injection of air (1905), but this can scarcely be applied in treatment of the trigeminal form on account of the resulting disfigurement in the face. Pitres of Bordeaux was the first to inject alcohol in treatment of facial neuralgia (1902), and this has now an extensive literature in all countries. At the best, however, its effect does not last more than nine months. Chavez reports a case in which the trigeminal neuralgia was not modified in the least by the neurolytic injections of alcohol nor by partial resections of the nerve. This patient

was a man of 50 and the neuralgia dated from 1910, although there had been occasionally mild neuralgic pains above the orbit from the age of 23. Year after year the whole array of treatment was applied in turn, including resection of the supra-orbital nerve. Retrogasserian neurectomy is the only resource now in this case, and he gives the minute details of the technic for this and the comments of various authors on this section of the sensory root of the nerve by Frazier's technic. (Published in *THE JOURNAL*, May 11, 1918, p. 1345.) Chavez describes further a case in which this operation was attempted for neuralgia of ten years' standing, refractory to all other measures. In detaching the meningeal artery from the base of the skull, there was severe hemorrhage which was arrested by ligating the middle meningeal artery. So much blood had been lost and the general condition was so bad in the woman of 62 that the operation was suspended, the patient dying six hours later. In another case the woman of 50 had continued to suffer from the neuralgia after resection of the ophthalmic and the superior and inferior maxillary nerves, and finally the gasserian ganglion was resected (Dr. de la Puente, July, 1917), the first operation of the kind in Peru. The patient died from hemorrhage after the gasserectomy.

Psychology of Insanity.—Delgado remarks that experience has shown the important part played by moral factors in the development of mental derangement; in fact, he deems this the principal factor. The new psychiatry, he declares, is based on psychology, while the textbooks and medical schools lead the student only a few steps into the vast field of psychologic processes. Psychoanalysis reveals that mental derangement may be caused by factors of a moral order, moral conflicts, and that the hallucinations, gestures and attitudes of the insane are all important clues for the psychologist, revelations of profound and vital significance for treatment. Of course every psychic process has its molecular concomitant, but Delgado reiterates anew "the priority of the function—the conception which is rejuvenating medicine in all its branches now." "Modern endocrinology is also demonstrating the connection between the psychologic activity and the somatic activity, and the influence of one on the other. Psychoanalysis has further shown the importance of organic inferiorities as factors in the psychogenesis of neuroses and psychoses, and in the physiologic estimation of the processes resulting from 'undrained' emotions."

Emergency Splenectomy.—Manchego removed the spleen of a boy of 14 on account of rupture and hemorrhage from a fall. The spleen was much enlarged from malaria, measuring 11 by 7 by 17 cm. and the tear was 8 cm. deep. Splenectomy is a comparatively common operation in Peru. In the case reported the liver began to enlarge the fourth day after the operation. If the tear in the spleen had been lower down, instead of in the upper pole, the boy would probably have bled to death before he reached the hospital.

Semana Médica, Buenos Aires

Oct. 30, 1919, **26**, No. 44

Proposed Reforms in Medical Course. P. J. García.—p. 509.

*Extremely Diluted Tuberulin in Treatment of Tuberculosis. F. Gómez Alvarez.—p. 516.

Origin of Univittelline Twins. M. Fernández.—p. 527.

*Roentgen Treatment of Bone and Joint Tuberculosis in Children. R. Espinola.—p. 533.

Tuberculin Prophylaxis and Treatment of Tuberculosis.—In this third instalment of his report, Gómez gives the details of ten cases of pulmonary tuberculosis systematically treated by the method of extreme dilution of the tuberulin. The bases for this treatment have already been summarized in these columns, as for instance, Feb. 23, 1918, p. 579. All Gómez' patients seem to be clinically cured at present.

Roentgen Treatment of Tuberculous Bone and Joint Disease.—Espinola declares that roentgen treatment is the best of all measures in surgical tuberculosis especially in cities. Surgical measures should be only secondarily considered. His experience with it has been very favorable, especially when the effect can be supplemented with heliotherapy and mountain or seaside climate.

Siglo Médico, Madrid

*Emotion. Ramón Turró.—p. 1073.

Personal Prophylaxis of Venereal Disease. E. Mañueco Villapadierna.—p. 1076.

Treatment of Gonorrhea in the Female. Sicilia.—p. 1079.

Vaccine or Tuberculin Treatment of Tuberculosis? R. Villegas.—p. 1080.

Emotions and Endocrinology.—Turró explains the psychic by the physiologic basis on which it rests, not the physiologic by the psychic, as is the general rule. Achúcarro's assertions in regard to an internal secretion of the neuroglia and Marañón's demonstration that the brain can influence the vegetative life in two ways, by both nerves and blood, have thrown much light on the question of emotions. Marañón has demonstrated that it is possible to induce all the phenomena of fright, such as pallor, dilatation of the pupils, acceleration of the heart beat, goose flesh, sweating, etc., without the intervention of the brain, merely by injection of epinephrin in the artificially hyperthyroidized or in subjects with latent hyperthyroidism.

*Research on Diabetes: II, III and IV. K. Sakaguchi.—p. 439.

Research on Diabetes.—Sakaguchi presents here his second, third and fourth reports on his exhaustive study of various features of diabetes. In the second he discusses why the tolerance of diabetics is the lowest at breakfast and the elimination of sugar the highest after this meal. His conclusion is that this is due to the fact that the production of glycogen is less after breakfast than at other meals. The elimination of sugar after breakfast can be reduced by giving a little carbohydrate or meat an hour or two before the breakfast. He states further that carbohydrates to the limit of tolerance are borne better if taken four or five hours after the preceding meal. When the interval is six hours or more, the glycosuria may be increased.

In his third communication he presents clinical evidence to show the injurious action of emotional stress on the sugar content of the blood, while brain work, without emotional disturbance, does not modify the glycemia. In the three cases described, the sugar content of the blood was determined before and after the patients had been informed of the serious nature of their disease. Diabetics should avoid occupations, he suggests, that entail worry or excitement.

The fourth communication discusses the influence of intake of albumin on the sugar content of the blood. As the considerable rise in the sugar content reaches its highest point in from two to four hours after eating meat, it seems to be due to the products of digestion in the small intestine, rather than to the products of putrefaction of albumin in the large intestine.

Differential Diagnosis of Gas Gangrene.—Stemmler emphasizes that there can be no hope of successful serotherapy of gas gangrene until we learn to differentiate it. Various kinds of lesions are now grouped under this heading. Typical gas gangrene is a general intoxication from infection of muscle tissue by anaerobic bacteria; the muscle tissue is destroyed by ischemia, never by putrefaction, as gas gangrene is not a putrefaction process, and should never be classed with such. There are two forms of typical gas gangrene, the bronze phlegmon and the epifascial form. Malignant edema belongs in this category of inflammation

from gas and edema-forming bacteria, although it is not of the true gangrene type. The two other categories of wound infection are inflammation from the pus formers, and inflammation from the putrefaction producers with formation of gas.

Stasis Hyperemia by Ligation of Femoral Vein.—Von Winiwarter was unable to obtain reliable results with a constricting band to the thigh in treatment of suppuration in the knee joint, and hence he resorted to ligation of the femoral vein, and reports encouraging results and knows of similar experiences in other hospitals. As the outcome thus surpassed expectations in these severe cases, he is inclined to extend the field of this procedure, and advocate ligation of the femoral artery whenever the fever keeps up for several days after the surgical toilet of the injured knee, and pus is found in the joint. It may be possible by this means to arrest the inflammation, and the lesion may heal without loss of function. As ligation of the femoral vein is a simple and harmless procedure it is justified, he thinks, in every case of severe infectious processes on the legs, in or outside of the knee. He urges others to give the method a trial, citing the details of his eighteen cases. All were war wounds. He applies the stout silk ligature to the vein just below Poupert's ligament, sometimes ligating another large vein besides the femoral. The cyanotic appearance has usually subsided by the next day, but the stasis edema persists. The relief from pain was striking, and even the change of dressings was not painful. The general condition improves, not only from the relief from the pain but from the shutting off of the septic products from the general circulation.

Goiter Operations.—Orth reviews his experience with 300 goiter operations; the mortality was 0.17 per cent. A number of cases showed the close correlation between the various endocrine glands which surgeons have to bear in mind; for instance, one woman first developed goiter after splenectomy. In another woman the goiter developed at once after removal of a myoma, while Wettergreen has witnessed the subsidence of a myoma as exophthalmic goiter developed. Several have reported increase in the size of the thyroid after removal of both ovaries, and Orth had a case in which the woman aborted three days after resection of the thyroid. Such happenings show the necessity for investigation of the genital organs before operating for goiter. In three cases a moderate form of tuberculosis seemed to be whipped up by removal of a goiter which had been compressing the trachea, and the patients soon died. Clairmont has reported some similar experiences with tuberculous patients. The blood pressure was high in 70 per cent. of Orth's cases, and after the thyroidectomy it dropped below normal, but gradually righted itself in a few weeks. No change in the coagulation of the blood was apparent. Transient albuminuria was evident in ten cases after the operation, not before. One patient had a spontaneous fracture of the femur a year after resection of the thyroid, and she died in six weeks. Orth is inclined to ascribe this fragility of the bones to abnormal conditions such as are observed in the bones of thyroidectomized dogs. The displacement of the trachea should be determined with radioscopia before the intervention as a guide to the operation. His only recurrences were in the four cases in which radioscopia had been neglected, and the protrusion of the goiter in the depths was not fully appreciated. He had fatal hemorrhage or embolism in two malignant cases, and in one case the esophagus was injured during the operation as also the trachea in another, but both healed without mishap after suture. Anomalies in the vessels were not infrequent, and this possibility should never be forgotten. In conclusion he warns of the necessity for caution in using disinfectants in this region; some have witnessed the flaring up of latent hyperthyroidism after application of iodized dressings, etc. Another danger from them is the effect on the vocal cords, similar to Cisler's experience with dogs; the vocal cords kept in the cadaver position when their innervation had been cauterized with silver nitrate. After thyroidectomy the vocal cords are liable to keep in the median position for a long time before

they resume normal movements, and any chemicals in the vicinity might exaggerate this.

Plastic Repair of Defects by "Suturing In."—Esser has been very successful with pedunculated flaps from the sound leg in operating on suppurating lesions that refuse to heal. When this technic is not applicable, he applies what he calls *Einnähen*, suturing the freshened defect, after excision of scar tissue, to some point on the sound leg. After it has grown to the sound tissues he cuts out one or two flaps and sutures the other edges to the defect. He gives illustrations of several particularly severe cases that healed under this "suturing in" procedure. None of the patients died.

Induced Pneumothorax in Lung Disease.—That indeed pneumothorax marks a distinct advance in the treatment of tuberculosis is the conviction reached by Henius after using it in twenty-four cases. He gives his indications for induced pneumothorax as follows: (1) unilateral tuberculosis with cavity formations, even though the other side shows a mild tuberculous infection, provided it is not progressive; (2) unilateral infiltrating inflammatory processes; (3) unilateral, cheesy pleuropneumonia; (4) hemoptysis, if the side that is bleeding can be ascertained; (5) pleuritis, with much effusion, replacing the fluid with air, and (6) a short trial in cases of unilateral, multiple bronchiectatic areas and a central lung abscess. Henius ascribes the good effects of pneumothorax not to the rest that the lung gets from collapse, but to lymph stasis and to hyperemia, which in turn induce renewed growth of connective tissue and thus initiate a healing process. Lymph stasis doubtless prevents the spread of the disease process and the resorption of toxic substances. Collapse of the lung causes also an abatement of the secretion, and pneumothorax gives the diseased lung an opportunity for healing by shriveling. He quotes statistics from Spengler, Saugmann, Stuertzel and Zinn, which go to show that over 25 per cent. of the patients so treated are symptomatically cured, and that from 40 to 50 per cent. more are benefited.

Glucose Injections in Heart Disease.—Pfalz found that infusion of glucose solution, as recommended by Büdingen in various heart diseases in which he postulates cardiodystrophy, affects the subjective symptoms favorably. In many cases he noted also objective evidence of improved heart action. No untoward effects have been observed thus far. Büdingen raised the question whether the nutritive material stored up in the heart and that brought to it by the blood are under all circumstances quite sufficient to enable the heart to perform the work that is expected of it. Büdingen began to consider whether or not in certain cardiac diseases, for example, in coronary sclerosis, the symptoms might be caused in large measure by faulty heart nutrition in consequence of narrowing of the blood vessels. He reached the conclusion that carbohydrates, and more especially glucose, play a larger part in heart nutrition than do protein and fat. The physiologic sugar content of the blood is from 0.07 to 0.11 per cent. (Ivar Bang), which suffices under ordinary conditions. The most important reserve product of carbohydrate metabolism is glycogen, the presence of which in the heart muscle is well known. Büdingen assumes that in certain conditions the heart fails to be adequately nourished, that the reserve of glycogen runs low and thus the heart does not get sufficient nourishment. The

resulting cardiodystrophy may be cardiogenic or ectocardiogenic. Coronary sclerosis is an example of the former type, in which both cause and effect lie within the heart. Pathologic conditions of the glands of internal secretion furnish an instance of the ectocardiogenic type, in which the cause lies without and the effect within the heart. Either type of cardiodystrophy Büdingen considers an indication for treatment with from 10 to 20 per cent. glucose infusions. Pfalz has used the Büdingen treatment in a number of cases, and states that he regards it as a valuable procedure. The technic is simple. He infuses a 12 to 20 per cent. glucose solution, prepared from chemically pure glucose tablets, and sterilized before it is used. Ordinarily, from six to ten infusions of from 200 to 300 c.c. each are given at intervals of a week. He gives the infusion at body temperature. He secured the best results in two cases of coronary sclerosis, combined with angina pectoris, with blood pressure only slightly above normal. At the end of the treatment the symptoms (oppression and pain in the chest and arm with suffocation after exertion) had almost entirely disappeared. In three cases of general arteriosclerosis with hypertonia and angina pectoris the infusions proved beneficial, in that the heart symptoms subsided considerably. The infusions raised the temperature in several cases, but normal temperature was promptly regained.

Progressive Paralysis.—The investigations of Jahnel, which showed that ordinarily there were large numbers of spirochetes present in the cerebral cortex of paralytics who had died during an attack, are confirmed by the researches of Jakob and Hermel. The findings of the latter investigators go to show that the exacerbations of the disease, considered from a parasitologic standpoint, constitute very important episodes in the course of progressive paralysis. As the most important results of his investigation, Jakob mentions finding that the mental and motor exacerbations are associated with regressive and progressive phenomena in the fundamental and essential part of the nerve fibers (the axis cylinder), and with severe inflammatory processes in the connective tissue, and infiltration of the pia, the vessels of the cortex and medulla; infiltration of cellular elements into the nerve tissue; collections of lymphocytes; encephalitic processes; occurrence of gummatous changes in the vessel walls, and of miliary gummata in the cerebral cortex. Also endarterial proliferation processes in the vessels of the cortex were noted. Jakob looks on his histologic investigations as furnishing further proof of the correctness of Jahnel's view that the exacerbations of the disease coincide with a vigorous and extensive multiplication of spirochetes. So much, Jakob thinks, must be taken as certain, that in progressive paralysis living spirochetes exert a direct effect on the brain.

It is still a question why paralysis develops in certain syphilitics and not in others, although the observation that it is the syphilitics with very slight defense reactions in whom paralysis appears seems to point toward a solution. Further light on the question is thrown by the observations of Erb and of Fournier that those in whom the infection takes a mild course and who present no specific skin lesions in the secondary stage are more prone to paralysis than are those of whom the converse is true. Jakob's histologic data give the clue to treatment of progressive paralysis. Everything possible must be done to effect a cure of the syphilis, to destroy the remaining foci of spirochetes, and to enhance the production of antibodies. He reports that efforts in this latter line are now under way. He is injecting patients by the vein with inactivated serum from untreated patients in the secondary stage of syphilis with pronounced cutaneous manifestations of the disease, hoping thus to increase the supply of specific antibodies. He is also planning to use cultures of the spirochetes for a similar purpose. As a further reinforcement of the treatment of progressive paralysis and other forms of severe neurosyphilis, he intends to try Knauer's method of injecting arsphenamin into the carotids. [This latter method was described in the *Münchener medizinische Wochenschrift* 66:609 (June 6) 1910. Even with this, the drug does not seem to pass into the cerebrospinal fluid, but the cell content dropped from 1,600 to 0 in one of the

nineteen patients thus treated. Knauer asserts that his experiments on the cadaver and on animals as well as his clinical experiences have demonstrated that this technic does not entail any considerable danger. He suggests that it might be combined with intraspinal injection of the drug, and that possibly mercury or other drugs might pass more readily than arsenic into the cerebrospinal fluid. He usually injects the drug into the carotid through the skin, without exposing the artery, as the patients are liable to tear off the dressings. The head has to be pendent, to throw the artery into relief. He says that in two of his cases no effect was apparent, but in the others the benefit surpassed that from any other treatment known to him.]

Myocarditis from Illuminating-Gas Poisoning.—Liebmann remarks that the publication of Zondek's studies on the heart findings after illuminating-gas poisoning impel him to publish the present case report. The unusual finding in Liebmann's case, which was that of a woman of 38 who was found unconscious in her bathroom, having been overcome by gas escaping from a gas heater, was a severe interstitial and parenchymatous myocarditis. Liebmann thinks that the symptoms in Zondek's case, the drop in blood pressure, the disturbances of the heart beat, and dilatation of the heart were doubtless the results of similar processes.

Experimental Pulmonary Edema.—What attitude does the healthy organism take toward the presence of fluid in the lung? In order to answer this question Laqueur undertook a series of experiments on cats and rabbits. A solution with which osmotic pressure would be especially active was chosen, in order that fluid might be drawn rapidly into the alveoli. He injected 1 c.c. of a 50 per cent. solution of glucose or of a 20 per cent. sodium chlorid solution into the trachea of a rabbit, whereupon edema of the lung shortly began to develop and continued to increase for about an hour, until the weight of the lung was three times the normal. Associated with the osmotic edema in the lung there was exudation into the surrounding serous cavities, especially into the pericardium. In all the fourteen instances of animal experimentation, at a certain period within the first two hours after injection, the hemoglobin content was higher than before the injection, so that it became evident that in osmotic edema, as well as in toxic edema, the blood undergoes inspissation. Through hemoglobin determinations it could be shown that the amount of fluid that passed out of the blood corresponded to the amount of fluid forming the edema. Induced edema of the lung appears, therefore, to be a ready means of not only bringing about changes in blood concentration but also of estimating the amount of such changes. Muscular rest was found to affect very favorably the course and final outcome of the edema. The circulatory disturbances are apparently suffocation symptoms. Respiration was accelerated but less profound, so that the total air inhaled was not changed. Laqueur thinks that the physical findings with such experiments may aid in teaching percussion and auscultation. Resorption in the lung after the injection was extremely rapid. Most of the fluid and of the glucose injected was absorbed promptly, the balance much more slowly. Osmotic equilibrium between the edema fluid and the blood serum was soon established.

Osteochondritis Dissecans.—Nigst remarks that the etiology of the disease of the joints in which pieces of articular

cartilage are split off from the ends of joints remaining otherwise intact is not yet fully cleared up, but the results of his radiographic investigations, together with the anamnesis, symptomatology and operative findings in his cases, are in close accord with the findings published by Ludloff in 1908. In view of the uniform, characteristic clinical picture he is inclined to regard osteochondritis dissecans as a distinct morbid entity. The various differences reported by other investigators correspond to the different stages of the same pathologic process. He agrees with Ludloff that the striking similarity in the localization of the lesions must be traceable to a definite disease process. The preliminary stages of the disease are as yet unknown, but if in all cases roentgenograms of corresponding joints were made, comparative studies could be undertaken that would help to throw light on the pathogenesis of the disease.

Silver Salvarsan Sodium in the Treatment of Syphilis.—Rille and Frühwald find that the effect of silver salvarsan on syphilitic symptoms, both clinical and serologic, is more rapid than that of the usual combined neosalvarsan treatment. Much smaller doses, they say, are required than are needed of other salvarsan preparations, which is all the more significant in view of the fact that silver salvarsan contains only two thirds as much arsenic as old salvarsan. In using silver salvarsan one therefore keeps well under the toxic doses. The authors found that as a rule silver salvarsan was well borne by patients; no serious accidents from its use were observed.

- *Blocking the Splanchnic Nerve. G. A. Preiss and A. Ritter.—p. 1025.
 Epinephrin not Indicated for Prevention of Postoperative Paralysis of the Intestines. Mülberger.—p. 1030.

Blocking the Splanchnic Nerves.—Preiss and Ritter report the application in 89 cases of Kappis' technic for blocking the splanchnic nerve from the rear, reaching it from just below the twelfth rib, at a depth of approximately 7 cm. above the second lumbar transverse process, introducing the needle at the lateral convex margin of the vertebra, and depositing from 10 to 40 cc. of a 1 per cent. procain-epinephrin solution. The patient may be prepared with a sedative the evening before and again half an hour before the operation. Wendling reaches the nerve from the front, 0.5 cm. to the left of the median line and 1 cm. below the xiphoid process, blocking the nerve before it joins the solar plexus. Four reports have been published of experiences with these methods, a total of 254 cases. Preiss and Ritter here state that in their 89 cases there were only 4 so refractory that the operation had to be done under inhalation anesthesia. Cancer involving the nerves was responsible for the failure in 2 of these cases and phlegmonous appendicitis in another case in which the parietal peritoneum was intensely sensitive. The fourth failure was with an ovariectomy; blocking the splanchnic nerves does not anesthetize the ovaries. In 5 other cases a little supplementary inhalation anesthesia was required. In one case the vena cava was punctured and in another the lung. Fifteen different types of operations were performed, including 13 resecting operations on the stomach, 5 gastro-enterostomies, 2 nephrectomies, 1 decapsulation of the kidney, 2 cholecystectomies and a large number of resections of the intestines, jejunostomy, etc. The fluid spreads easily in the retroperitoneal tissues, so that a single injection on each side was all that was needed for the appendicectomies. The results were better when Kappis' solution was modified to the following: 1 c.c. procain; 50 c.c. distilled water; epinephrin (suprarenin) 0.001; sodium chlorid 0.35, and potassium sulphate 1.2 c.c. The anesthesia was so complete that they finally dispensed with the preliminary sedatives as superfluous and even detracting from the anesthetic effect. The youngest patient was 11, the oldest 70. No serious by-effects were noted, no signs of intoxication or collapse, at most occasional nausea and pallor during the

operation, exceptionally a little vomiting. The special field for splanchnic anesthesia, they affirm, is not only for major operations on all the organs of the greater abdominal cavity but also interventions for severe acute peritonitis, as after perforation of a viscus.

Zentralblatt für Gynäkologie, Leipzig

Dec. 6, 1919, 43, No. 49

*Helminths in Female Genital Organs. F. Tschamer.—p. 989.

*Nasal Diphtheria in the Newly Born. J. Becker.—p. 996.

Helminths in Female Genital Organs.—Tschamer reports a case in which two living specimens of the oxyuris were found in the right tube after total hysterectomy. As the tube was slit, one of the helminths crawled to the mouth of the tube, the other to the fimbriated end and both dropped off. The longest was 12 mm. in length. No ova of the oxyuris could be detected anywhere in the excised mass, but it had been rinsed, and possibly some may have been present at first. The woman had been recently treated with santalin on account of discomfort from itching at the anus and genitals and in the nose. The pinworms probably had found their way from the anus through the vulva and uterus into the tube, but there did not seem to be any pathologic condition for which they could be held responsible. The patient in this case was a previously healthy secundipara of 31 who had had a hydatidiform mole removed in 1909; another in 1919 compelled evacuation of the uterus anew. The genitals were otherwise normal at the time, but five months later she returned complaining of pains in the inguinal region and excessive menstrual hemorrhages, and a nodular tumor was found low in the uterus, apparently a chorio-epithelioma. Tschamer reviews the literature on helminths in the internal genitals; it is evidently a very rare occurrence. He was not able to find any previous record of the penetration of the helminths or ova beyond the vagina and cervix except that Marro reported in 1901 a case in which oxyuris ova were found in a cyst on an ovary.

Nasal Diphtheria in New-Born Infants.—Becker states that at the Jena maternity there were five cases of nasal diphtheria in new-born infants in 1918 and four in 1919. He warns that bacteriologic examination is indispensable for every case of coryza in a young infant and above all when the discharge from the nose shows traces of blood. In one case the nasal diphtheria entailed general sepsis with mixed infection and necrosis of the arm. The snoring breathing is the first symptom to attract attention, and then the thin, slightly purulent discharge running from one or both nostrils. It is often reddish or brownish, and erodes the upper lip. The membranes are generally far back in the nose, but can be easily removed. Becker ascribes the infection to carrier visitors as the most probable source. On this account it is now the rule not to give the child to its mothers to nurse during "visiting hours," and no outsider is allowed in the infants' ward. In a recent compilation of thirty-eight cases the mortality was 31.6 per cent., mostly from complications. In another case the diphtheria settled in the cord.

Dec. 13, 1919, 43, No. 50

*The Other Tube with Tubal Pregnancy. C. U. v. Klein.—p. 1001. Id. R. Meyer.—p. 1007.

Transperitoneal Cervical Cesarean Section with Premature Separation of the Placenta and Contracted Pelvis. D. Eberle.—p. 1010.

The Other Tube with Tubal Pregnancy.—Klein discusses the best method for preventing further conception in operating for tubal pregnancy, saying that simple ligation of the other tube does not accomplish this nor even excision of a piece of the tube. He has had cases of pregnancy later after both these procedures, and he describes a case of a second tubal pregnancy in the other tube which had been ligated at the first operation. The changes in the tube in consequence of the ligation had evidently afforded a predisposition for embedding of an ovum in the tube. Hence he advises in operating for tubal pregnancy to leave the other tube unmolested, unless time can be taken to render it permanently impermeable, by excision and burying the stump in the uterus wall. Anything less than this may

actually invite tubal pregnancy later. If it is deemed best to shut off the other tube, he advises Madiener's method as the most promising of the rapid procedures, that is, to shut off with ligatures a crushed loop of the tube. Klein's experience with eighty cases of extra-uterine pregnancy includes thirty-two in which sterilization was attempted.

Dec. 27, 1919, 43, No. 52

*Eclampsia and the War. W. Gessner.—p. 1033.

Rieck's Resection of the Uterus. D. Pulvermacher.—p. 1036.

Eclampsia and Wartime Conditions.—Gessner states that the official statistics for Baden show a proportion of from 1.5 to 2 cases of puerperal eclampsia per thousand births between 1910 and 1916, inclusive. In 1917 the births numbered only 29,779, in comparison to the 60,621 in 1914, but the cases of eclampsia showed a still greater proportional decline, there being only 0.8 cases per thousand births. Baden is the only one of the German states that has compiled statistics on eclampsia, but various obstetricians have commented on the proportional drop in the number of cases of eclampsia. At the Hannover maternity eclampsia dropped from 25 cases in 1913 to 23, 13, 10 and 7 during the years of the war. He ascribes this decline in eclampsia to the women's working and exercising more under war conditions rather than to the wartime restrictions in diet, though the latter helped to combat the dangerous accumulation of fat. If the lack of fat and protein were responsible for the falling off of the cases of eclampsia, then cows would never have eclampsia. But cows do have eclampsia, he says, because they are phlegmatic and lazy, and this allows fat to accumulate. As soon as the troops scattered to their homes and the women ceased to be active breadwinners, the old conditions returned, so that the factors keeping down eclampsia no longer prevail. There is every reason to expect, he reiterates, that the eclampsia curve will rise and will never again touch such a low point as in 1918.

The obesity resulting from thyroid or pituitary deficiency was not modified by war conditions, and women with this did not grow thin during the war. Pregnant women of this "fat anemia" type are peculiarly predisposed to eclampsia unless they are given thyroid or pituitary treatment in time. He adds that the war experiences have demonstrated on a huge scale that women exercising and working to the last, and living on a scanty diet, have shorter and easier labor because there are no hindering subperitoneal layers of fat, as under other conditions, and the children are smaller. He explains that the reason why there were any cases of eclampsia during these recent years was that women of means were not obliged to work, and the extensive contraband trade lessened the dietary restrictions for many women.

Zentralblatt für innere Medizin, Leipzig

Dec. 27, 1919, 40, No. 52

*Effect of War Undernutrition on the Bones. A. Koepchen.—p. 961.

War Pathologic Conditions in Bones.—Koepchen comments on the reports which came in first from Vienna, in the spring of 1919, on the peculiar endemic pathologic condition in the bones, resembling rachitis or osteomalacia. Reports soon followed from other points in Germany and Austria, Tübingen, Frankfurt, Breslau, Bonn and Dresden. In his own experience, in the Rhine-Westphalia district, he encountered twenty cases in a few weeks, all in men except three, and inquiry elicited a large number of similar histories throughout the region. All were in young people, and all were of the poorer classes. The combination of severe pains in the bones, edema and a hemorrhagic tendency, and the characteristic light roentgen shadows of the bones and the endemic character, with negative findings in other respects, distinguish this war osteopathy. Influenza cannot be incriminated, as nothing of the kind seems to have been observed in the countries of the Allies, or after preceding epidemics of influenza. It is probably the result of a qualitative starvation of bone tissue, from chronic lack of certain necessary food elements. As he was unable to obtain cod liver oil, he gave merely phosphorus and calcium and found this effectual, the pains in the bones becoming attenuated in a few

days as a rule, only a few not feeling the benefit for a week or two. He cites nineteen reports on the subject in German-Austrian journals.

Nederlandsch Tijdschrift v. Geneeskunde, Amsterdam

*Deformity of Chest from Asthma. A. A. H. van den Bergh.—p. 1245.
A Practical Stomach Pump. H. Wigger Boelens.—p. 1251.

*Asphyxia of the Newly Born. P. J. Mink.—p. 1253.

*Colic from Acute Angioneurotic Edema. J. H. Landwehr.—p. 1259.

The Tetrahedron Chest.—Van den Bergh says that he has not found any reference in the textbooks to the malformation of the chest which he describes with illustrations. It suggests a solid with four sides, each an equilateral triangle, the chest projecting in a peak between the nipples. His five patients with this deformity had suffered since childhood from attacks resembling severe asthma, and the strain from these attacks explains the protrusion of the chest and its final persistence in this pyramidal shape. There was no history of rachitis in any instance. One of the patients was a man of 31 and another a boy of 11.

Asphyxia of the Newly Born.—Mink does not accept Kouwer's theory in regard to intra-uterine movements of the fetal respiratory muscles. He insists that the fetal air passages are collapsed, and there can be no lumen. The glottis and the nostrils are also closed. The small arteries are contracted also, as is inevitable when there is no respiration. This is an additional factor in the anemia of the central nervous system. Other factors are the pressure on the head and chest in the birth passages. Respiration is inaugurated, he explains, by the sinking of the diaphragm. The traction from this pulls on the trachea and opens it, and this in turn pulls on the glottis and opens it and the nostrils. The respiration releases the arterioles from compression; they dilate, and blood streams to the respiration center, and the latter then takes charge of the respiration process. He reiterates that when the ordinary stimuli from the mechanical and other changes after delivery are inadequate, tickling the nasal mucosa might prove a potent means to act on the respiration center. As it is vitally important to supply the respiration center with blood, he advises not to cut the cord until after this stimulus has been applied to the nose. Very little time is lost by this, while the mother's blood may turn the scale. If not, the cord can then be cut and the Schultze swinging started. The swinging is merely, he thinks, a strong stimulus to the skin, and irritating the nasal mucosa is an equally potent stimulus. The great importance of this stimulation of the nasal mucosa is best appreciated by comparing the normal nose breathing with breathing through the mouth or tracheal cannula. The lack of the normal stimulus from the nose may be one of the causes of the asphyxia. The excitability of the respiration center at birth may be enough to start respiration, but may not be enough to maintain it when the normal stimulation from the nose is lacking.

Acute Angioneurotic Edema.—In the case reported by Landwehr in a previously healthy woman there was fleeting edema at various points, but each time the edema subsided in about half an hour, not leaving a trace. Eyelids, lips, chin, arms, hands and feet were affected in turn, and finally sudden stormy symptoms indicated that the fleeting angioneurotic edema had attacked the bile ducts, simulating actual gallstone colic. This has occurred on two occasions to date. The swelling of the mucosa of the bile ducts obstructs the flow of bile, and the retention causes the colic pains the same as from retention of other origin. The case is still under treatment. Arsenic, strychnin and quinin have been recommended, with regulation of the bowels and a milk-vegetable diet. The first signs of the edema were noted about four months before date of writing.

*Abscess in Lung after Tonsillectomy. H. Burger.—p. 1359.

Prognosis of Scarlatinal Nephritis.—Duyvis protests that scarlatinal nephritis does not altogether deserve the bad reputation it has acquired. Recent reexamination of 30 nephritis patients from the epidemic of scarlet fever at Amsterdam in 1906, showed normal kidney functioning in 21 cases. The blood pressure was normal in 5 others who presented intermittent albuminuria, including one suspected of tuberculosis. In 4 others the blood pressure was above normal, and there were traces of albumin in the urine. All of the 30 were in good general health. Not one of the 30 had actual nephritis, and none had died from nephritis in the interim.

Correction of Crooked Nose.—De Flines gives illustrations before and after his correction of "rhinodystasia," congenital or acquired, and describes his technic for this "rhinorthosis" by cutting a wedge-shaped piece out of the upper jaw, on the broader side of the nose, working through the nose and subcutaneously, so there is no scar. The apex of the triangular wedge resected points upward, reaching nearly to the orbit. The bone on the other side is reached in the same way but merely a linear incision is made on this side, slanting from the orbit outward, and the same length as the corresponding side of the wedge on the other side. The nose is then pushed over into its normal place. In doing this, the bony connection with the frontal bone has to be wrenched apart or fractured. He does this with the thumbs both on the small side, and has always succeeded without using instruments. The nose is then modeled, and fastened in its new position with a stout silk thread passed through a hole in the jaw on the broad side and in and out through two holes in the septum, thus pulling the whole nose over into its proper place. He operates under local anesthesia throughout, as also when he merely removes redundant bone to transform an ugly hook nose into an esthetic profile.

Vasotomy.—Klots merely describes this operation "as done by the Americans."

Triplet Birth.—A viable 8 months girl was delivered and then two dead male twins from a second ovum at about the fifth month. This case confirms the assumption that triplets are generally from two ova.

Lung Abscess Following Tonsillectomy.—Burger reviews the literature that has accumulated on this sequel of tonsillectomy since Manges first called attention to it in 1916. He thinks that the possibility of blood-borne infection cannot be excluded, but emphasizes that lack of preparation for the operation may also be a factor. Recovery after long convalescence is usual, but operative intervention has sometimes been necessary, opening and draining the abscess, or resection of the lung. Cott lauds artificial pneumothorax as the most effectual measure in treatment. Burger remarks in conclusion that the data cited confirm the necessity for remaining in bed under medical supervision for a few days after tonsillectomy; also the necessity for the employment of local anesthesia for older children and adults, and in young children the special precautions which every general anesthetic should impose.

*Mammary Cancer. A. Neander.—p. 937.

Mammary Cancer.—Neander analyzes the experiences at Stockholm with 427 operations for mammary cancer between 1900 and 1914. The 330 radical operations were followed by recurrence in or near the site of the cancer in 165 cases, and only 19 per cent. were living free from recurrence after three years; 28 patients were thus apparently definitely cured. After five years these figures were 16.8 per cent. and 23. The outcome is not known in 84 cases. The immediate operative mortality was 2.1 per cent. He reiterates that 75 per cent. at least of all pathologic conditions in the female breast after the age of 30 are malignant. He discusses the arguments for and against evacuation of the supraclavicular fossa, saying that the 15 patients on whom this was done all died from cancer. Over 66 per cent. of all recurrences developed in or near the old site.

PROTEIN DIETS AND UNDERNUTRITION IN TREATMENT OF DIABETES

FREDERICK M. ALLEN, M.D.
NEW YORK

The modern treatment of diabetes is generally recognized as an attempt to relieve overstrain of a weakened assimilative function by limitation of the diet. In the more severe cases, such relief is most quickly and thoroughly obtained by fasting, either immediately or after a preparatory fat-free diet as proposed by Joslin. This part of the program is usually the simplest for successful accomplishment, and the chief difficulties and chief causes of varying results in the hands of different practitioners are found in the arrangement of the subsequent diet. Excess in total calories has been the commonest mistake and responsible for much unfavorable progress and mortality, as pointed out in the comparison of cases differently treated by different persons in the Rockefeller Institute series.¹ But the proportions of various foods are also highly important for maintaining control of the diabetes with the least possible impairment of health and strength. Some practitioners desiring to avoid the former evils of high protein-fat diets have gone too far toward the opposite extreme with diets excessive in vegetables and deficient in protein and calories. Mosenthal² has outlined diets predominant in protein and emphasized protein as the most important food for maintaining body nitrogen. Equilibrium is known to be possible at widely different levels of nitrogen, total calories and body weight. If active symptoms are to be prevented, the therapeutic problem in each individual patient is to determine the diet which gives the most beneficial nutritive result without overtaxing the assimilative power, the latter being taken as the standard rather than any arbitrary nutritive level.

At the Rockefeller Institute hospital, the diet after fasting generally began with a carbohydrate tolerance test, in the form of a regular addition of 10 gm. of carbohydrate in vegetables daily until glycosuria resulted. The purpose was to establish a standard of tolerance for comparison of different cases and of the same case at different times, and to continue under-nutrition while diminishing or abolishing acidosis.

Such a program is really feasible only in an experimental institution, and objections to it may be thus formulated: First, the time consumed is often so great as to be an obstacle to general practical application. Second, during this period there is relative protein starvation combined with a special strain on the carbohydrate assimilation, both of which are better avoided if possible. Third, it is now known both from the clinical experience and from animal experiments³ that relief of the injurious overstrain of the assimilation requires control not only of glycosuria but also of hyperglycemia. A test based only on glycosuria therefore sets a false standard, and is subject to considerable errors through the wide variations of renal permeability.

Five facts may serve for guidance in planning diets after fasting: (a) The total calories at first should be very low and increased gradually. (b) Protein is the most important food. (c) The tolerance for protein is highest when other foods are excluded or closely restricted. (d) The caloric requirement falls with the body weight and may reach a very low minimum.⁴ (e) The tolerance rises as the weight falls; and with exceedingly few exceptions the two curves intersect at some level on which life can be supported.

In a few cases with severe acidosis, a short carbohydrate period may be advisable. But for most cases in private practice it has seemed advantageous to use almost pure protein diets until the blood sugar falls to normal, and then gradually to build up a maintenance diet to such a level as is possible without return of hyperglycemia or marked acidosis. The severity of the diabetes and the quantity of protein that can be tolerated may best be judged by a protein tolerance test as described by Jacobsen,⁵ which is especially useful in some cases for deciding whether the patient is breaking diet. Or, without any formal test, a satisfactory routine is to begin with a small protein allowance and determine the blood sugar occasionally as a guide for the increase. Under any conditions, the ultimate criterion of the severity of diabetes is the level of diet and body weight which can be endured without return of symptoms. The application of the method in question may be illustrated by the following summaries of case records, selected chiefly with reference to some of the practical difficulties.

MILD DIABETES WITH OBESITY AFTER MIDDLE LIFE

CASE 1 (36).—*History.*—A married woman, aged 55, admitted to the hospital, July 30, 1919, with negative family history except for obesity in the father and one brother, had worked hard and was thin up to age of 26, when she moved to America. Here she married and gradually became pros-

perous and obese. Five children were born to her; there was fever for two months following the birth of the first. One miscarriage occurred at the age of 40; she refused curettage and suffered from profuse menstrual hemorrhages thereafter. A year or two later she began to suffer chronic pains in the joints, especially the knees, which still continue. Five years before admission she was in bed with fever for three weeks; the physicians diagnosed infected uterine fibroids and were on the point of operating when the condition improved spontaneously. Hemorrhages ceased at menopause at about the same time and a small umbilical hernia was discovered which, though retained by a belt, has grown larger and creates much inconvenience. She had complained of "stomach trouble" for the last twenty-five or thirty years, with pain when hungry, generally relieved by food, but sometimes with cramps after eating. There had been continuous slight pain and tenderness in the liver region, and physicians had diagnosed an enlarged liver. She had been a large eater all this time, but denied excesses in sweets. Five years before admission she reached her highest weight of 274 pounds. Pruritus, polydipsia and polyuria then came on, and diabetes was diagnosed about one year later. Lax diet stopped the glycosuria temporarily, but it returned. Three years before, severe neuritis of the right leg kept her in bed for seventeen weeks; it was over a year before she could walk straight, and slight pain still remained. During this time her physicians used only local treatments, without diet restriction. Her weight had been diminishing, and she had become highly neurasthenic. Her complaints on admission were weakness, loss of 16 pounds in weight in the last two weeks, polyuria, pruritus, indigestion with abdominal pain, pelvic pain from fibroids, joint pains, neuritis in the right leg, inconvenience from hernia, and exaggerated nervousness with frequent crying spells.

Physical Examination.—The patient's height was 5 feet, 7 inches, and the weight, 212 pounds. The knee-jerks were absent and the Wassermann test was negative. Other findings were as indicated in the foregoing history.

Treatment.—In addition to heavy sugar, the urine showed traces of albumin but no acetone. After twenty-four hours of fasting, the glycosuria diminished to a faint trace, acetone did not appear, but the plasma sugar was still 0.4 per cent. A diet was begun of 10 gm. of carbohydrate, 50 gm. of protein and 400 calories; glycosuria ceased within another twenty-four hours. August 4, the plasma sugar before breakfast was 0.214 per cent., and the diet was increased to 70 gm. of protein, 20 gm. of carbohydrate and 650 calories. August 9, the carbohydrate was increased to 40 gm., and August 13 the patient was discharged on a diet of 70 gm. of protein, 50 gm. of carbohydrate and 900 calories; the plasma sugar was 0.144 per cent. and the body weight 103 pounds. Occasional slight nitroprussid reactions were present in the urine. Most of the pains and other subjective symptoms had disappeared; there was no complaint of indigestion on the low diet; the strength had improved with the aid of outdoor walking; with the better general condition the distress from the enlarged liver, hernia and fibroids was much less, and the patient felt well and cheerful.

Subsequent History.—August 20, the patient reported, with urine negative for sugar and acetone, but plasma sugar 0.254 per cent.; she was still feeling well. She admitted some laxness in diet, and was admonished to be strict. At her second visit, August 29, the plasma sugar was 0.183 per cent.; September 15, it was 0.152 per cent. The weight fell below 200 pounds, though the diet was gradually increased to 1,500 calories, and the patient had taken minor liberties in addition. The plasma sugar, November 24, was 0.190 per cent., and the patient was urged to be more strict.

The case illustrates the variety of ailments that may result from overeating and obesity. Both for these and for the mild diabetes there is naturally indicated an undernutrition diet containing protein to protect body nitrogen and carbohydrate to prevent any serious acidosis, but deficient in fat so as to compel burning

of body fat. The high renal threshold for sugar shows the unreliability of urine tests as a guide for treatment. The best policy calls for a normal blood sugar; but in view of the age of the patient and the inherent mildness of the diabetes, no undue alarm need be created by moderate hyperglycemia, especially as the analyses after discharge were all taken during digestion. Operation has been suggested for the hernia and possible gallstones if the patient will first reduce her weight sufficiently, but she will probably remain satisfied with her present condition.

MODERATELY SEVERE DIABETES AFTER MIDDLE LIFE

CASE 2 (42).—History.—A man, aged 58, married, manufacturer, admitted, Aug. 2, 1919, with negative family history except for slight obesity in the father and mother, had had scarlet fever at 12, which was his only illness. There was no history of alcoholism or of excesses in food or sweets. Slightly obese from boyhood, he reached his highest weight of 210 pounds four years before. Then he had an acute onset of weakness, and a physician immediately diagnosed diabetes. The diets prescribed were unable to stop the glycosuria and loss of weight; pains in the legs became very troublesome, and in April, 1919, he was referred to me for treatment. He was given general instructions for a diet adequate in protein and low in both carbohydrate and fat, on which glycosuria was absent but hyperglycemia persistent. Instead of improving, he complained of increasing languor. An examination, July 29, revealed a very faint stigar and negative nitroprussid reaction in the urine, with plasma sugar of 0.395 per cent. It was evident that mistakes in the diet at home were subjecting the patient to semistarvation without corresponding benefit, and he was accordingly brought into the hospital, August 2.

Physical Examination.—The patient's height was 5 feet, 8 inches, the weight, 137 pounds. The teeth were much decayed and repaired. The knee-jerks could be barely elicited with reenforcement. The examination was otherwise negative.

Treatment.—The patient insisted on staying as short a time as possible in the hospital. On a diet of 70 gm. of protein, 10 gm. of carbohydrate and 700 calories, the plasma sugar fell to 0.181 per cent., August 7, and moderate nitroprussid reactions were constantly present. With increase of fat to make 1,200 calories, these reactions became heavier and the plasma sugar rose to 0.192 per cent. The patient was dismissed in this condition, August 16, weighing 132 pounds and feeling slightly better. On attempting to work, he became weak and had an attack of indigestion, which alarmed his family so that they brought him back to the hospital, August 22, and persuaded him to stay for more thorough treatment.

On a diet of 40 gm. of protein, 10 gm. of carbohydrate and 1,000 calories, the plasma sugar fell to 0.136 per cent. September 1. Also the blood urea, which had been 52.2 mg. per hundred c.c., fell to 26 mg. The diet was gradually built up, so that the patient by September 30 received 70 gm. of protein, 50 gm. of carbohydrate and 1,400 calories (reduced one seventh by weekly fast-days). The last plasma sugar tests showed 0.147 per cent. fasting and 0.181 per cent. during digestion. The blood urea was 22.8 mg. per hundred c.c. There were constantly slight nitroprussid reactions in the urine. The weight was 128 pounds, and there was a decided improvement of strength and well-being and an absence of pains. The patient was dismissed, October 3, with a reduction of carbohydrate to 30 gm. as a precaution against errors of diet at home.

Subsequent History.—Owing to well-meaning mistakes, the plasma sugar has since varied from 0.115 to 0.277 per cent. It has not been feasible to increase the diet or the weight. The improvement in health has continued, and the patient performs the light duties of his business and asserts that except for some lack of endurance he feels as well as ever in his life.

The case illustrates the frequent difficulties of home treatment even in willing and intelligent households, and the necessity of sufficiently long and thorough supervision and instruction in order to obtain results. It is also an example of the greater or less discomfort and disability which usually result from diabetes even in later life. The case may be classed as moderate in severity, on the basis of the restrictions of diet and weight required. Undernutrition has improved the strength and comfort as well as the prognosis, but the results can never be as good as if thorough treatment had been begun at an earlier stage.

CASE 3 (6).—History.—A man, aged 62, married, lawyer, admitted, July 23, 1919, whose father died at 67 of tuberculosis, mother at 67 of cancer, three uncles of tuberculosis, and a grandmother of acute nephritis, and in whose family there was no record of diabetes or obesity, had passed a very healthy life except for childhood diseases. In 1901 an attack of urinary "gravel" incapacitated him for three days. An intense attack in 1911 terminated with the passage of a stone the size of an orange seed. He had a mild attack of "grip" five years before, but was not subject ordinarily to colds. He was moderate in all habits, and his highest weight had been 195 pounds. For the last two years he had noticed gradually increasing loss of weight and strength, polydipsia, polyuria, irritability of temper, and aching in the legs. A physician consulted in June, 1919, diagnosed diabetes and referred the patient to me for treatment.

Physical Examination.—The patient was 5 feet, 11 inches in height and weighed 138 pounds when dressed. The general examination proved negative except for thinness and heavy glycosuria with slight acetoneuria.

Treatment.—Instructions were first given for an approximate diet to be taken at home, guessed to represent about 60 gm. of protein and from 20 to 30 gm. of carbohydrate, with as little fat as possible. Glycosuria ceased within a week, but notwithstanding further restrictions of diet and loss of weight, hyperglycemia persisted, and glycosuria returned whenever an increase of diet was attempted. The patient entered the hospital, July 23, weighing 133 pounds, with negative sugar and slight nitroprussid reactions in urine, and plasma sugar of 0.214 per cent. On a diet of 40 gm. of protein and 10 gm. of carbohydrate, heavier nitroprussid reactions developed, and the plasma sugar, July 28, had fallen to 0.115 per cent. This rapid fall of blood sugar may be attributed partly to the more accurate restriction of diet as compared with that at home, and partly to the preceding month of undernutrition. The diet was rapidly increased to 80 gm. of protein, 20 gm. of carbohydrate and 1,500 calories (reduced by weekly fast-days to about 70 gm. of protein and 1,300 calories average). The patient was discharged thus, August 8, with plasma sugar before breakfast of 0.127 per cent. and negative sugar and moderate nitroprussid reactions in the urine. His weight was 130½ pounds.

Subsequent History.—The patient was rigorously faithful, but there were various minor mistakes in his household, so that later the plasma sugar was found to range from 0.106 to 0.234 per cent. Matters improved after a dietitian took charge of his kitchen for two weeks. The weight fell to 116 pounds stripped, but it was possible to increase the diet to 30 gm. of carbohydrate and 2,000 calories, generally with only 60 gm. of protein because of the patient's distaste for it. The weight thus rose to 119 pounds. The plasma sugars during digestion in the forenoon have ranged from 0.148 to 0.197 per cent. Attempts to increase the diet or weight have resulted in glycosuria and increased ketonuria. Nitroprussid reaction in the urine now remain negative. The patient has been maintained at the level stated in the hope of improvement with time.

In all probability the diabetes in such a case existed in mild form for a number of years before the beginning of noticeable symptoms. At the time of initial treatment, the decline of health and strength was

becoming rapid. The benefit usually felt when diabetes is checked by diet was about balanced by the under-nutrition imposed, so that the patient feels about the same as before treatment. He still carries the full work devolving on him as a prominent lawyer, which he probably could not have done if the diabetes had continued unchecked; but he remains thin, weak, and subjectively unimproved. The chief claim to be made for treatment lies in the prognosis, which can generally be considered good at this age. Overfeeding to the point of marked hyperglycemia and glycosuria damages the prognosis in such a case without building up strength. On the other hand, insistence on rigidly normal blood sugar, necessary in youthful cases, is here unnecessary. For the sake of strength the diet has been pushed to the point of moderate hyperglycemia, and there is hope of falling blood sugar and rising tolerance with time. Though there have never been any symptoms of acute danger, the reason for calling this fairly severe diabetes is the low tolerance, which in six months has not permitted raising the weight above 119 pounds.

SEVERE DIABETES IN MIDDLE LIFE

CASE 4 (25).—History.—A man, aged 43, unmarried, wholesale liquor dealer, admitted, Aug. 4, 1919, whose father died with diabetes at 77, whose mother was well at 72, and who had two brothers and four sisters who were well, and one brother who had epilepsy, stated that mild childhood infections, and gonorrhea at 20, had been his only illnesses. He had eaten three ordinary meals a day and a lunch every night, and was guilty of no excesses in food, alcohol or tobacco. He had always been thin, with an average weight of 115 pounds. In 1917 he experienced loss of weight without other symptoms, and a physician diagnosed diabetes. A diet low in carbohydrate without restriction of protein and fat kept sugar absent for six months, but glycosuria had been present most of the time since, and he had suffered from weakness, loss of weight, polydipsia, polyuria, nervousness, dental caries and inflammation of the gums.

Physical Examination.—The patient's height was 5 feet, 2½ inches, and weight 86 pounds. He was delicate and nervous in appearance, but did not present acute symptoms. The teeth showed much repair, and though scrupulous cleanliness had been maintained by frequent washes and a dentist's care, the gums were everywhere red, very dry, and covered with small, superficial ulcers. There was slight dulness of both lung apices anteriorly and posteriorly, but no active signs of tuberculosis. Knee-jerks were absent. The blood pressure was 84 systolic and 66 diastolic.

Treatment.—Fasting, with the usual clear soup, bran, and agar jellies was begun at entrance on the morning of August 4. The plasma sugar on the morning of August 5 was 0.350 per cent. With continuous fasting to August 12, the urine still showed slight sugar and nitroprussid reactions. There were no signs of danger, and the plasma bicarbonate remained high. The weight had risen by water retention to 89½ pounds. August 13 and 14, a diet of 30 gm. of protein and 135 calories was given. The remaining traces of glycosuria then ceased with a single fast-day, August 15. The plasma sugar was then 0.231 per cent., and the carbon dioxide capacity 69.2 per cent., with nitroprussid reactions positive in the urine but negative in the plasma. August 16, a diet of 10 gm. of protein was begun, increased by 10 gm. daily. Glycosuria appeared with 50 gm. of protein, August 20, and continued on reduced diet, so that fasting was necessary August 23 and 24. An increasing protein diet was again attempted, and glycosuria appeared with 60 gm., August 30. After a fast-day, the plasma sugar on the morning of September 1 was 0.208 per cent. On that day a diet of 60 gm. of protein and 900 calories produced glycosuria, which required two fast-days, September 2 and 3, to stop. On the morning of September 4 the plasma sugar was 0.106 per cent. As such

a rapid fall under such circumstances may be a sign of serious weakness, the diet of 60 gm. of protein and 900 calories was resumed, with the result of slight glycosuria and on the morning of September 6 a plasma sugar of 0.288 per cent. A single fast-day, September 7, brought another sharp drop of the plasma sugar to 0.120 per cent. on the morning of September 8. Thereafter a diet of 30 gm. of protein and 500 calories was tolerated without glycosuria and with only occasional traces of nitroprussid reactions, but the plasma sugar, September 15, was up to 0.238 per cent. It fell by September 20 to 0.120 per cent., and after a fast-day, September 21, to 0.086 per cent. September 22. The diet was then increased to 50 gm. of protein and 700 calories, and by September 27 the plasma sugar had risen to 0.165 per cent. After a fast-day, it was down to 0.130 on the morning of September 29. Though the patient appeared scrupulously faithful and, furthermore, was under close observation, it was deemed prudent to make sure whether his diabetes was actually so severe or whether there was any smuggling or deception. Accordingly, September 29, Dr. Jacobsen⁶ performed a protein test, and it was found, with the patient sitting constantly in the laboratory, that the ingestion of 50 gm. of protein in beefsteak sufficed to raise the plasma sugar to 0.203 per cent. in six hours.

Continued undernutrition, in the form of a diet of 50 gm. of protein and 800 calories, with weekly fast-days, reduced the plasma sugar to 0.079 per cent. on the morning of October 13. About this time the body weight reached its lowest level of 69 pounds. The patient, though very feeble, was always out of bed several hours a day. An increase to 60 gm. of protein and 1,000 calories was now tolerated without hyperglycemia. The diets up to this point had consisted strictly of protein and fat, without thrice-cooked vegetables or any possible source of carbohydrate other than a few bran biscuits. October 20, it was possible to proceed to a diet of 60 gm. of protein, 5 gm. of carbohydrate and 1,200 calories. November 1, the patient was discharged on a diet of 70 gm. of protein, 10 gm. of carbohydrate and 1,500 calories; also the weekly fast-days were mitigated by an allowance of 20 gm. of protein and 5 gm. of carbohydrate. The plasma sugar was 0.118 per cent. The weight was 73 pounds, and the patient was up all day and able to take walks.

Subsequent History.—The patient returned to his home in another state, and was able to carry on his private affairs, though remaining practically an invalid. He came back for examination, December 12, with his general condition as at discharge, though distinctly stronger. Sugar and nitroprussid tests were negative in the urine, and the plasma sugar taken at 10:30 a. m. was 0.152 per cent. This figure, during digestion of breakfast and under the stress of traveling, was regarded as a basis for continuing the same diet.

Even in the absence of acute symptoms at admission, the severity of the diabetes makes it probable that it would cause early death if not controlled. The severe measures used were necessary for controlling such a case. When the last traces of glycosuria are unduly persistent, the initial fast may profitably be interrupted by a few days of low protein diet. The subsequent program consists in feeding chiefly protein to keep up the strength as well as possible, while waiting for undernutrition to lower the weight and raise the tolerance. The undernutrition may thus be carried to a point which might otherwise be dangerous, though in such desperate cases it is always necessary to be on the watch for threatening collapse. The skilful use of soup, coffee, agar, bran, celluloflour⁷ and other materials of little or no food value is an important aid against suffering from hunger. The result in this case was as good as could be expected under the conditions. The teeth and gums

were quickly brought to normal, and the trouble from diabetes is now limited to emaciation and weakness. The patient is comfortable as a semi-invalid, and much pleased with his present feelings as compared with the former state of active diabetes. The question remains open how long this condition can be maintained.

POTENTIALLY SEVERE DIABETES IN YOUNG ADULT

CASE 5 (70).—History.—A man, aged 28, married, carpenter, admitted, Oct. 6, 1919, whose parents were living and well, knew of no heritable disease in the family. Three brothers and two sisters of the patient died in infancy of unknown cause. His wife and two children were well. He had measles, mumps, chickenpox, whooping cough and diphtheria in childhood. Then he was well until 1912, when he had severe typhoid with three relapses, being dangerously ill in bed for fourteen weeks. Since then he had had vague umbilical and lumbar pains about once a week, not related to meals, which came on especially if he maintained a stationary position, and were relieved by exercise. Jaundice or clay-colored stools were never noticed. He had had regular habits and had eaten heartily in his occupation as a carpenter, chiefly at outside work. He reached his highest weight of 160 pounds during convalescence from typhoid, and thereafter maintained an ordinary weight of 145 pounds. Three weeks before admission his weight was found to be only 137 pounds; he had a severe acute rhinitis with headaches, followed within two days by distinct onset of polyphagia, polydipsia and polyuria. The physician, who was called immediately, diagnosed diabetes, but prescribed lax diets, largely of milk and eggs, on which active symptoms and loss of weight continued.

Physical Examination.—The patient's height was 5 feet, 9¼ inches; his weight, 126 pounds. He was tanned and muscular, and appeared healthy except for moderate thinness. There was marked cervical adenopathy. The kneejerks were normal. The examination was otherwise negative.

Treatment.—Glycosuria ceased with two days of fasting, while the slight ketonuria increased. From an original 0.357 per cent. the plasma sugar fell rapidly to normal and remained so on a diet of protein alone, beginning with 30 gm. and increasing to 70 gm. October 13, the diet was made 70 gm. of protein, 20 gm. of carbohydrate and 1,200 calories, and increased, October 20, to 70 gm. of protein, 40 gm. of carbohydrate and 1,500 calories. The plasma sugars before breakfast ranged from 0.100 to 0.114 per cent., but one reading taken two hours after lunch was 0.187 per cent. Nevertheless, as the patient was in a hurry to leave, he was discharged, October 26, in the hope that he would improve further.

In the short hospital period he had not become sufficiently impressed with the necessity of exactness, and at home committed several minor indiscretions which caused glycosuria; and though this was checked by fasting and reduced diet, the plasma sugar remained high, and he was therefore readmitted to the hospital, November 27.

Injury to the tolerance was evident, for on a diet of 30 gm. of protein and less than 300 calories the plasma sugar fell slowly to 0.172 per cent., December 1, and 0.110 per cent., December 6. It remained thoroughly normal while the diet was gradually built up through the ensuing weeks to 70 gm. of protein, 30 gm. of carbohydrate and 1,650 calories, on which the patient was dismissed, January 22, weighing 128 pounds.

The pancreatic damage probably dates from the typhoid infection. Glycosuria presumably began some time between this and the first observed diabetic symptoms. The severity of the diabetes was still moderate at admission, but relapse was quick owing to the slight impression made by a short hospital period. The instruction in testing the urine for sugar proved important, as an effectual danger signal was thus given. The longer second period in the hos-

7. An indigestible cellulose flour, still on a somewhat experimental basis, produced by the Dietetic Cellulose Laboratory, 2557½ West Chicago Avenue, Chicago.

pital established a safer condition on a higher diet. The weight is lower than at admission, but stationary instead of falling. The patient is strong enough to work, but the caloric requirements of manual labor constitute a problem in a case having the elements of severity.

THE EARLY STAGE OF INHERENTLY SEVERE DIABETES IN YOUTH

CASE 6 (61).—History.—A youth, aged 19, a dealer in antiques, unmarried, admitted, Oct. 3, 1919, whose mother and one aunt had diabetes, had a healthy life and excellent habits. There was slight obesity. He had measles in childhood, malaria three years before admission, and influenza in the fall of 1918. During the first week of September, 1919, he noticed onset of weakness, polyphagia, polydipsia and polyuria. After steady loss of weight, he consulted a physician, September 25, who discovered heavy glycosuria and prescribed a carbohydrate-poor diet. Glycosuria rapidly diminished so that only a trace was present at admission.

Physical Examination.—The patient's height was 5 feet, 6 inches, and weight, 143 pounds. The patient appeared in good health and nutrition, and normal to all examinations.

Treatment.—After one day of fasting, glycosuria was absent and the plasma sugar was 0.134 per cent. The first day's diet was only 10 gm. of protein, increased by 10 gm. daily to 60 gm., October 8. The urine showed slight to moderate nitroprussid reactions during this time. Carbohydrate was then added, first 10 gm., increased to 40 gm., so that by October 11 the nitroprussid test was negative. The plasma sugar before breakfast, October 13, was 0.106 per cent. Up to this point fat had been so strictly excluded that the highest diet had not been above 500 calories. Fat was now introduced to make 1,000 calories, and increased by October 20 to 1,500. The occasional faint nitroprussid reactions thus produced were ignored. The highest plasma sugar observed was 0.149 per cent. during digestion in the afternoon. The patient was discharged, October 24, on a diet of 70 gm. of protein, 40 gm. of carbohydrate and 1,500 calories. His weight was then 136½ pounds.

Subsequent History.—The patient resumed his regular work and was strictly faithful to diet. The urine remained normal except for occasional faint nitroprussid reactions, but there was difficulty with the blood sugar, such as is frequently encountered shortly after patients return home. In samples taken forenoons during digestion, the highest plasma sugar found was 0.192 per cent., and the lowest 0.150 per cent. The diet was therefore reduced to 60 gm. of protein, 20 gm. of carbohydrate and 1,200 calories, with weekly fast-days. The body weight has thus fallen to 130 pounds, but the plasma sugar does not exceed 0.14 per cent. It will be required to remain below this level during digestion of all meals, and below 0.12 per cent. fasting, even if more weight has to be sacrificed. The patient meanwhile continues his regular work, looks distinctly thin, is a little below full strength and not completely satisfied in his appetite, but never suffers actual hunger.

It is hoped that a diet of 1,500 calories may soon be tolerated; but it is believed that the case represents the early stage of inherently severe diabetes, and that any overfeeding which would give an appearance of increased well-being at the price of hyperglycemia would prove disastrous. A longer period of hospital treatment would have been advantageous. The principal lesson, however, is the strict care which is necessary even in an incipient case, and the irremediable downward progress that would result from depending on urine examinations and ignoring the signs of overtaxed function evident in the blood.

JUVENILE DIABETES IN STAGE OF MODERATE SEVERITY

CASE 7 (44).—A boy, aged 5, admitted Aug. 31, 1919, whose parents and two brothers were well, though both grand-

fathers and the paternal grandmother had diabetes, had always been a vigorous, active child, plump but not obese. Measles at 3 years had been the only illness. He was not subject to colds or tonsillitis and indulged in no excesses in sweets. He had an infected wound of the face in May, 1918. Jan. 12, 1919, his mother noticed polyphagia, polydipsia and polyuria, and found that his weight had diminished by 2 pounds. The physician found 7 per cent. glycosuria, and treatment was begun at once. A two day fast produced sugar freedom, and carefully restricted diets were used thereafter, but glycosuria kept returning at frequent intervals. The weight at onset was 38½ pounds, and it had increased to 42½ pounds. During the last month glycosuria had occurred every few days, and the patient was referred for treatment on this account.

Physical Examination.—The patient was a well developed, handsome child, apparently in perfect health and nutrition. He had left cervical adenopathy, supposedly the result of the face wound. The knee-jerks were normal and the Wassermann test negative. Examination was otherwise negative.

Treatment.—The urine was free from sugar, but showed continuous heavy nitroprussid reactions. The plasma sugar before breakfast was 0.120 per cent. September 1, a diet of 50 gm. of protein was begun, and from September 2 an addition of 10 gm. of carbohydrate was made daily, while fat was excluded as far as convenient. September 9, glycosuria appeared with 80 gm. of carbohydrate, while slight nitroprussid reactions still persisted. No fasting was imposed, but the foregoing program was repeated, and glycosuria returned when the increase of carbohydrate reached 60 gm. September 16, the nitroprussid reactions had become faint. A diet was then begun of 60 gm. of protein, 45 gm. of carbohydrate and 600 calories, with weekly fast-days. The plasma sugar, September 20, was 0.102 per cent. As a skilled diet nurse was available, the parents were allowed to take the child home at this stage. The weight was 39 pounds.

Subsequent History.—September 28, the plasma sugar before breakfast was 0.15 per cent. Unduly high figures continued thereafter, notwithstanding a temporary reduction of diet to 40 gm. of protein, 20 gm. of carbohydrate and 450 calories. Attention was then given to the fact that the office visits involved a long automobile ride from the home in the country, with some attendant excitement; and by keeping the child over night at the hospital, normal sugar values have been obtained both fasting and during digestion. The nitroprussid tests are continuously negative. The child holds an even weight, 3 or 4 pounds below that at admission. He still looks well and is active, but yet is weaker as well as thinner than when received, and the fast-days are especially depressing. The diet is now being gradually increased, and gain of strength is to be expected if a sufficient ration can be tolerated.

The physician in charge had succeeded in keeping this child in an appearance of perfect health and strength during one year of diabetes, and also the plasma sugar before breakfast was normal. The overprosperous appearance had been maintained by the liberal use of fat. The tolerance had now fallen so that glycosuria was increasingly frequent from the small quantities of carbohydrate employed. At the same time there was marked continuous ketonuria, even though the plasma bicarbonate was still normal. Continuance of the high fat diet involved three possibilities: If the carbohydrate should be diminished, the acidosis would increase; if the carbohydrate should be continued the same, the increasing glycosuria would soon bring still greater acidosis; if the carbohydrate should be increased, it would give a temporary diminution of acidosis at the price of a rapid breakdown of assimilation followed by the most dangerous acidosis of all. Therefore the program adopted was to exclude fat, to give 50 gm. protein for maintaining strength, and to take advantage of the increased tolerance gained by undernutrition for the purpose of pushing

carbohydrate so as to abolish acidosis. This result was slow and difficult to attain, because the excess in fat had been so long. The only benefit of the treatment to date has been the clearing up of glycosuria and acidosis, at the price of a certain amount of weight and strength.

The expectation now is to add to the diet so far as possible without a return of hyperglycemia or ketonuria. Some degree of thinness is inevitable from the nature of diabetes, but the family, especially the mother, hold the ideal of a fat child. Though the child does not now appear pathologically thin to a casual observer, this insistence on fattening is likely sooner or later to ruin the entire result in this case.

This case is presented as illustrating some of the practical difficulties of treatment. A diabetic child is not a well child and is often irreparably injured by the attempt to keep it appearing like a well child. Without hazarding a prediction of the ultimate outcome, there is now firm basis for two assertions concerning the possible benefits of thorough treatment of juvenile cases from the earliest stage: first, the three year limit of life no longer holds; second, comfort and happiness are greater than when active diabetic symptoms are permitted. As the diabetes is not cured, these benefits are purchased at a price. For the child, this is continuous undernutrition corresponding to the severity of his diabetes. For the household, the presence of an ailing child who is known to be incurable, the constant exact care of the diet or the keeping of a nurse for the purpose, and the nervous tension associated with the various vicissitudes and tests, constitute a serious burden. Obviously, this is no worse than the situation existing with many forms of chronic disease. With mothers of the old-fashioned type, it is possible for the child to receive correct care for an indefinite period with little disturbance of the home life. Some records of favorable progress and longevity, illustrating the brighter possibilities of juvenile diabetes, may be published later.

Half-measures are hopeless in children. It is fair to ask that those who believe in high diets should follow them consistently, and not merely through the mild stage when temporary weight and comfort are so easily maintained at the price of irremediable injury and subsequent suffering. If thorough control of the diabetes is the policy chosen, normal urine and blood should be insisted on from the time of the earliest diagnosis, for only thus can the best prognosis along with the best lasting nutrition be attained.

SEVERE JUVENILE DIABETES

CASE 8 (23).—*History*.—A schoolboy, aged 15, admitted Aug. 5, 1919, with family and personal history negative, had always been fat, while both parents were spare built. In January, 1918, it was first noticed that he was losing weight. He was taken from school and given abundance of milk and nourishing food; intense polyuria and polydipsia developed. The curious feature was that several urinalyses by the family physician and one by a commercial laboratory were reported negative, and no diagnosis was made until, in May, 1919, failing vision sent him to an oculist, who diagnosed double diabetic cataract and referred him to a consultant, who found 4 per cent. glycosuria. The weight, which had originally been 96 pounds, remained above 75 pounds up to this time, and then began to fall rapidly. Finally the patient was taken to a hospital in desperate condition, July 14, and subjected to fasting, but sugar-freedom was found. Difficult and heavy glycosuria returned with every attempt to feed. In consultation, July 31, there were found heavy sugar, nitroprussid and ferric

chlorid reactions in the urine, blood plasma creamy with fat, plasma sugar 0.441 per cent., and carbon dioxid capacity 68 per cent. by volume. The last figure was largely explained by the use of alkali; the plasma gave a heavy nitroprussid reaction. Weakness and emaciation were extreme but not actually critical. Alternation of fasting and very low protein diet was advised. The patient was transferred, August 4.

Physical Examination.—The boy's height was 5 feet 6 $\frac{3}{4}$ inches, his weight 66 pounds. Except for emaciation, cataracts and absent knee-jerks, examination was negative.

Treatment.—The urine at admission showed only slight sugar and nitroprussid reactions. The plasma sugar was 0.410 per cent., the carbon dioxid capacity 76.8 per cent. by volume. There was no visible lipemia, and only a faint nitroprussid reaction in the plasma. Notwithstanding the serious weakness, fasting was continued from August 4 to 12, with only thin soup, coffee and agar jelly, bran being omitted for fear of its possible carbohydrate. The renal permeability was peculiar, for while only traces of glycosuria, too small to titrate, were present at admission with plasma sugar of 0.410 per cent., these traces continued with plasma sugar, August 12, of 0.259 per cent. August 13 and 14, 30 gm. of protein and whisky to make 300 calories were given daily, with resulting gain of strength and fall of the plasma sugar to 0.205 per cent. A trace of glycosuria was still present, but ceased on fasting with whisky, August 15. The same program was continued, August 16. Whisky was then stopped, and protein alone given, August 17, 20 gm.; August 18, 30 gm.; August 19, 40 gm. Slight glycosuria then resulted, with plasma sugar of 0.250 per cent. It was then attempted to keep the protein at 25 gm. and increase calories with fat to 600; but glycosuria with plasma sugar of 0.268 per cent. resulted, August 23. With a single day of fasting and whisky, August 24, the plasma sugar fell to 0.188 per cent. A diet of 15 gm. of protein and 400 calories was then given for a week, and, August 31, the first fast-day without glycosuria was given; the plasma sugar before it was 0.192 per cent., and after it 0.150 per cent. The same diet with weekly fast-days was continued, and the plasma sugar after the fast-day of September 7 was 0.127 per cent., and after the fast-day of September 14 it reached the normal level of 0.115 per cent.

The diet was gradually increased to 30 gm. of protein and 700 calories, without glycosuria and with only faint traces of ferric chlorid reactions, notwithstanding the strict exclusion of carbohydrate. In spite of the long undernutrition, the weight tended to rise by invisible water retention, and, October 15, reached its highest point of 72 $\frac{1}{2}$ pounds. The strength improved correspondingly, and the boy was out of bed all day. Also, October 3, the more advanced cataract was uneventfully removed, and no retinitis found behind it. The clear vision of one eye in place of the former almost complete blindness contributed most of all to the patient's happiness. But the plasma sugar after the fast-day of October 12 was up to 0.192 per cent., and the calories were therefore reduced to 500, leaving the protein at 30 gm. After October 20, 5 gm. of carbohydrate was given daily. The plasma sugar before breakfast, October 25, was 0.155 per cent.; after the fast-day of October 26, it was 0.125 per cent. It was 0.097 per cent., October 31, and the diet was therefore increased to 30 gm. of protein, 10 gm. of carbohydrate and 600 calories. The plasma sugar was 0.12 per cent. on the morning of November 10, but gradually rose to 0.174 per cent., November 19. The carbohydrate was therefore diminished to 5 gm. On this diet, plasma sugars before breakfast were obtained as follows: November 29, 0.139 per cent.; December 5, 0.128 per cent.; December 10, 0.142 per cent. With a view to improving strength, the diet was changed to 40 gm. of protein and 600 calories, and later increased to 50 gm. of protein and 650 calories. This regimen has continued to the present. The plasma sugars have held about the same slightly elevated range of values as stated. Even on salt-free diet to remove edema, the weight has not fallen below 67 pounds, which is 1 pound above the entrance weight. Both sugar and nitroprussid reactions are continuously negative in the urine.

Unfortunate delays in the diagnosis of diabetes are still encountered even among practitioners of good repute, but are becoming less frequent. The damage in such a case is irreparable. The boy remains emaciated, weak and always more or less hungry. It is inconceivable that he should live to maturity, and during life he is cut off from practically all normal pursuits. Favorable features in his treatment may be thus enumerated: Actual suffering from hunger is prevented by the use of materials to furnish bulk (bran, agar, cellulose, "India gum," liquid petrolatum, soups, small quantities of thrice boiled vegetables), without which such low diets would scarcely be practicable. The boy has become strong enough to keep the average hours of a normal boy, and to go walking or riding every day, his pedestrianism amounting to 6 or 8 blocks without weariness.

Operations may be performed with safety, and wounds heal well when diabetes is controlled even at this extreme stage; therefore the sight of one eye could be restored and the same can be done for the other at the proper time. Having exceptional artistic talent, the boy now is able to keep himself constantly amused with drawing and painting. He has a naturally cheerful disposition, and though an invalid, his continuous enjoyment of life is genuine and not pretended.

Such cases suggest the possibilities open when thorough treatment is employed from the earliest stages.

SUMMARY

A possible form of low-calory diet after fasting is one composed wholly or chiefly of protein, and this plan has seemed to be most useful for maintaining strength during the period of undernutrition necessary for attaining a normal blood sugar. In some elderly patients slight hyperglycemia and nitroprussid reactions may be permissible to avoid undue hardships, but diabetes after the age of 40 is by no means always benign, and not infrequently requires stringent measures to control it, especially after long neglect. The more severe the diabetes and the younger the patient, the more rigorously should hyperglycemia and all other symptoms be controlled from the outset. Such a policy often means a considerable reduction of weight and strength as compared with the level which can be maintained temporarily by higher diets, and its justification depends on the belief that patients are best off in the long run when their weakened function is spared as thoroughly as possible.

5 East Fifty-First Street.

Alcoholic Hair Tonics.—Assurance of 100 per cent. cooperation in the enforcement of the prohibition laws were given by representatives of the barbers' supply and perfumes trade organizations at a hearing before Prohibition Commissioner John F. Kramer and officials of the Bureau of Internal Revenue to discuss ways and means for rendering certain alcoholic preparations now on the market undrinkable. After Jan. 16, 1920, the date the national prohibition act becomes effective, such preparations cannot be legally manufactured or sold if fit for beverage purposes. Dr. A. B. Adams, chief chemist of the Bureau of Internal Revenue, declared there are on the market many hair tonics whose principal ingredient is alcohol and that they are hair tonics in name only. Such preparations must be modified to conform to the law. The bureau has under consideration a requirement that in the manufacture and sale of hair rum there be added a quarter of a grain of tartar emetic for each fluidounce.—*United States Bull.*, Dec. 8, 1919.

THE FEEDING OF NORMAL INFANTS DURING THE SECOND YEAR

JOHN LOVETT MORSE, A.M., M.D.

Professor of Pediatrics in the Medical School of Harvard University
BOSTON

Whether or not it has been nursed or fed artificially, a baby, when it is a year old, will be taking, in most instances, whole milk or whole milk with a cereal diluent. If it follows the present fashion, it will almost certainly be receiving orange juice in addition. It will probably be taking some of the simple cereals and perhaps broth and beef juice. If it is being fed properly, it will not, in my opinion, be given anything else.

NEED OF CEREALS AFTER FIRST YEAR

If the baby is not getting cereals when it is a year old, they should be given at once. The simplest and most digestible cereals are barley jelly, oat jelly and farina. They should be given at the beginning of two feedings daily with milk and salt, but no sugar. Cream should never be given to babies, and sugar is unnecessary. It is idle, of course, to say that a little sugar will do harm. Almost all babies and children are, however, fond of sugar, and the tendency of almost all children is to take more sugar and sweets and to refuse foods that are not sweet or sweetened. The most common cause of indigestion in childhood is sugar and its products. If the baby is taught from the first to eat things without sugar, it learns to like them in this way and, as it grows older, is willing to eat proper food. Much trouble in the future is thus avoided if babies are never given sugar or sweet foods. Cream of wheat, Ralston and rice may be given after a few months, and it is not necessary to strain the oatmeal after the baby is 18 or 20 months old. Cereals that are not cooked in the house and the sweet cereals should never be given to babies.

BROTH AND BEEF JUICE

If the baby is not already receiving broth and beef juice, these should be given at the beginning of another feeding when the baby is a year old or soon after. Chicken and lamb or mutton broth are much more digestible than beef broth. Not more than 4 ounces should be given at a feeding, because of the danger of "filling up" the baby and destroying its appetite for more nutritious food, the value of clear broth being practically nil. The expressed beef juice is far preferable to any other form. Not more than 2 teaspoonfuls should be given at first, and never more than 2 ounces before the end of the second year, because beef juice makes many babies nervous and sleepless. It must not be forgotten in this connection that the nutritive value of beef juice is only about half that of an equal quantity of milk.

ZWIEBACK, BREAD AND RICE

A month or two after broth and beef juice have been started, zwieback, bread crumbs and rice should be given in them. If the baby has a sufficient number of teeth to enable it to chew properly, it may be given zwieback, toast bread, stale bread or plain white cracker "in its hand" to eat after one or more feedings. It should never be given these things between feedings, because it is of great importance for the baby to acquire early the habit of eating only at meal times.

Bread and crackers may also be given in milk or in the form of milk toast or cracker milk toast in place of, or in addition to, the cereal at the last meal of the day.

LAXATIVES

It is probably advisable, although not usually necessary, to continue the orange juice, especially if there is a tendency to constipation. If there is, prune juice or pulp and baked apple may be given instead of, or in addition to, the orange juice. The orange juice should be given an hour before some feeding, and prunes and baked apple at the end of some feeding.

Plain boiled macaroni, preferably riced, may be added to the diet at 15 or 16 months. At this time, or a little earlier, the milk at the midday meal may be given in the form of junket or plain blanc mange. It is most unwise, I believe, to begin potatoes before the baby is a year and a half old. Throughout infancy they should be given only when baked, and then sparingly. There is apparently no other form of starch so hard for the baby to digest and so likely to cause fermentation.

THE USE OF EGGS

It is also unwise, in my opinion, to give eggs before the baby is eighteen months old. Half an egg may then be given once or twice a week, and a little later a whole egg three times a week. In my experience, few babies can take more without being disturbed. If babies can take eggs without disturbance, a number of other articles that are made with eggs can then be added to their diet. These are baked custard, rice pudding and bread pudding. Eggs should be given to babies coddled, soft-boiled, dropped or poached and in no other ways.

MILK AS THE BASIS OF DIET

Milk should form the basis of the diet during the second year, and an important part of the diet for several years longer. It is probably wise to limit the amount of milk to a quart daily. This quantity provides enough nourishment to cover a considerable part of the caloric needs. If more is taken, it is likely to destroy the appetite for other articles of food.

MEAT AND GREEN VEGETABLES

The diet outlined above is all that is necessary or advisable for the average, normal infant up to the end of the second year. At this time I add meat to the diet and sometimes green vegetables. Ordinarily, however, I wait some months longer before adding the green vegetables. The most easily digested meats are the white meat of chicken, lamb chop and scraped beef. These are, therefore, given first. The most easily digested vegetables are, in my experience, spinach, string beans, peas, asparagus and stewed celery. The spinach, string beans and peas should always be rubbed through a sieve or a colander. Carrots are much less digestible and should always be mashed. My subject, however, is the diet of the normal infant during the second year, and infancy ends with the close of the second year. I must not, therefore, further consider any articles of diet that, as I believe, should not be given until infancy is passed.

THE LIBERAL DIET

I am well aware that the diet which I have outlined is old fashioned and that many, perhaps the majority, of pediatricians and practitioners feed much more

liberally. I know that many give green vegetables to babies that are artificially fed when they are only 6 months old. Some of them may give them also to breast-fed babies. I do not know. I know that many give eggs and meat at a year and feed babies of 2 years more liberally than I would feed children 4 or 5 years old. Why is it that so many pediatricians feed babies so much more liberally than was the custom some years ago? Are there any good reasons for the change, or are they blindly following a new fashion? Do the babies do any better when they are fed so liberally, or do they thrive better when they are fed simply? If they do better on one system than the other, why do they? If they do not, why do they not? Ought those who feed simply to adopt the newer and more liberal methods, or ought those who feed so liberally go back to the simpler methods of their elders?

It is very difficult to answer these questions on the basis of clinical experience. My own experience has been that babies thrive on the simple diet that I have outlined. The not inconsiderable number of babies brought to me because they are not thriving on the liberal diets prescribed by other pediatricians convinces me that some babies, at least, do not do well on these liberal diets. These babies do well, however, when given simple diets, which would seem to show that the simple diet is better and that the babies which do well on a liberal diet do so in spite of the diet rather than because of it. I have no doubt, on the other hand, that other men may have seen babies which were not doing well on the simple diets prescribed by me and which did well at once on the more liberal diets that they ordered. They would, of course, draw entirely different conclusions from their experience than I would from mine. Would either of us, neither of us or both of us be justified in our conclusions? I am inclined to think neither of us.

WHAT NATURE TEACHES US

Does Nature teach us anything of value as to the solution of this problem? Very little. As Nature provides a supply of breast-milk sufficient under normal conditions for the needs of the baby for nearly a year, it seems evident that Nature did not intend breast-fed babies to have eggs, meat and green vegetables when they were 6 months old. Nature teaches us nothing, however, as to what the baby should eat after it is a year old or what an artificially fed baby should have to eat during the first year, except the general indications afforded by the composition of human milk. These are that the baby's digestive powers are best fitted to take care of a dilute food relatively high in fat and carbohydrates and relatively low in proteins, with the protein in an easily digestible form. It would seem reasonable on the basis of these indications to believe that artificially fed babies should be given a simple diet along these lines rather than a diet that makes demands on the digestive powers for which they are apparently not fitted. We are, nevertheless, not justified in drawing too definite conclusions as to what indications Nature gives us as to the feeding of babies, as is shown by what we know of starch. There is no starch in human milk, and it would seem, therefore, as if a baby could not digest starch. Nevertheless, we have found that the power of starch digestion is well developed at birth, and that babies have no disturbance of digestion when mod-

erate amounts of starch are added to their foods. We must be careful, therefore, in drawing conclusions from what Nature seems to teach us as to the artificial feeding of babies.

IS THE SIMPLE DIET SUFFICIENTLY NUTRITIOUS?

Rather than to attempt to prove at once that the simple diets are preferable to the more liberal, it seems to me better first to ask what arguments those who believe in the liberal diets are likely to advance in their favor. It seems to me that they may claim that the simple diet is not sufficiently nutritious; that it does not contain a sufficient amount of certain elements, such as vitamins and salts, necessary for the well-being and development of the baby, and that it tends to the development of constipation, while their liberal diet corrects all the deficiencies of the simple diet. They certainly cannot claim that the liberal diet is more digestible than the simple diet. It is self-evident that it is not, and it must be admitted without question that whatever advantage there may be in easy digestibility lies with the simple diet.

Let us take up first the nutritiousness of the diet; that is, its caloric value. The caloric needs of the average baby of a year are at a liberal estimate not over 1,000 calories daily and of a baby of two years not over 1,200 or 1,300 calories. The quart of milk which is recommended in the simple diet provides 670 of these calories. Two or three tablespoonfuls of cereal, a slice of bread and the juice of an orange will bring the total up to 1,000 calories. If there is no lack of calories in the simple diet at the beginning of the first year, there will certainly be no lack later, when the diet is increased. The protein needs of babies in their second year vary between 20 and 30 gm. daily. A quart of milk contains 34 gm. It is evident, therefore, that the simple diet outlined amply provides for the caloric needs of babies in the second year and more than covers their protein needs.

THE VITAMINS

Now as to the argument that the simple diet may not contain enough vitamins, or accessory food factors: The fat of milk contains an abundance of the fat soluble A. If a baby takes a quart of milk daily, it will have no lack, therefore, of this element. Milk is also rich in the water soluble B. A baby that takes a quart of milk will thus also be amply provided with this element. It will, moreover, get a certain amount of these elements in its other food. Judging from the fact that babies grow satisfactorily on an exclusively milk diet during their first year, it seems reasonable to believe that milk contains a considerable amount of the hypothetic growth vitamin. A quart of milk daily will presumably furnish enough of this in the second year. Milk is known to be low in antiscorbutic power. Nevertheless, a pint of milk contains enough antiscorbutic element to prevent the development of scurvy during the first year. A quart of milk would be expected to furnish enough during the second year. If the baby is taking orange juice, moreover, the question of the antiscorbutic power of the rest of the diet will never arise.

MINERAL SALTS

The salts which may reasonably be considered in this connection are those of calcium, phosphorus and iron. The average amount of calcium retained by

infants is between 0.17 and 0.18 gm. daily. One liter of cow's milk contains from 1.65 to 1.98 gm. of calcium oxid.¹ Other figures given are that infants require 5 grains of calcium daily, and that a quart of milk contains 22 grains.² Next in calcium content come eggs; then the cereals, especially rice; then some of the vegetables, such as radishes, asparagus and spinach. Foods poor in calcium are meat, fish, bread, fruits and potatoes. It is evident, therefore, that the baby that gets milk will not suffer for lack of calcium. Furthermore, eggs and cereals contain more calcium than do the vegetables.

Milk contains so much more phosphorus than the baby can possibly utilize that it is not necessary to consider this element further.

I have been unable to find any figures as to the needs of babies for iron. A liberal estimate of the adult's need of iron is 0.015 gm. daily. Taking the average weight of the adult as 150 pounds and that of the average baby between 1 and 2 years of age as 25 pounds, the infant's requirement will be one sixth of the adult's, or 0.0025 gm. daily. Milk is a food notoriously low in its iron content. Nevertheless, a pint of milk contains 0.0009 gm. of iron, and a quart 0.0018 gm. of iron, or more than two thirds of a baby's daily needs. An ounce of beef juice contains 0.00198 gm. of iron. The value of this iron is, however, probably not as great as it would seem to be, because the iron contained in hemoglobin and its derivatives is very poorly absorbed. The yolk of an egg contains 0.0015 gm., three tablespoonfuls of cooked cereal 0.0009 gm. and one and one-third slices of bread 0.0003 gm. of iron. It is quite evident, therefore, that the baby taking the simple diet will not lack for iron. Furthermore, the iron content of the green vegetables is not as great as would seem from their color. An ounce of fresh spinach contains 0.00094 gm. of iron; 1 ounce of string beans, 0.00047 gm.; and 1 ounce of carrots, 0.00023 gm. These figures have been calculated from the tables given by Carter, Howe and Mason.³ Moreover, it would seem more reasonable, provided the simple diet did not contain enough iron, which it does, to give the baby some preparation of iron than to take the chance of upsetting the baby's digestion by giving green vegetables. The argument which may be raised by some that the iron in the green vegetables, being organic, would be better utilized is erroneous, because it has been conclusively proved that organic and inorganic iron are equally well utilized.

THE NEED OF BULK

Now as to the question of constipation: It is true that green vegetables act as laxatives by increasing the bulk of the intestinal contents and perhaps also by certain irritating elements stimulating intestinal peristalsis which they may contain. Bulk is not lacking, however, in the simple diet, for milk provides a considerable residue. Orange juice, prune juice and baked apple are as good laxatives as green vegetables and less likely to disturb the digestion. There is, therefore, not likely to be any necessity for the use of the green vegetables for the relief of constipation.

THE SIMPLE DIET VINDICATED

The arguments that it was thought might be advanced by the believers in the liberal diets against the simple diet in favor of the liberal diets have, therefore, no basis in fact. What other explanation can there be of the present tendency to increase the diet so rapidly during the latter part of the first and the second year of life? It can be traced back to the time, I think, when the majority of physicians in this country accepted without question and without thought everything that came from Germany. German babies were given sausages and sauerkraut; consequently they believed that American babies ought also to take them. Another possible reason is the general tendency of physicians, especially young ones, to believe that everything which is new is right and everything which is old is wrong. Physicians are in general altogether too willing to accept any new teaching as true, if it is new or different. This, to my mind, is wrong. We should not discard the old and tried in favor of something new, simply because it is old, and should not accept the new until it has been proved to be better than the old. We must not forget that there are fashions in medicine as well as in dress, and that the new fashions are often no improvement on the old. On the other hand, we must be open-minded and be willing to accept the new when it is better than the old and not reject it because it is new. I have tried to be open-minded on this question of diet for babies during their second year, but perhaps I have not succeeded. My conclusion after due consideration, observation and experience is that the old fashioned simple method of feeding is better and safer than the newer and more liberal diet.

THE DIAGNOSIS OF HEART DISEASE
IN YOUNG PEOPLE *

PAUL D. WHITE, M.D.

BOSTON

One of the most important lessons that the civilian physician learns from his army experiences is the need of more accurate diagnosis of heart conditions in young people. A discussion of this subject is particularly apropos at the present time, because still fresh in our minds and still fresh on the pages of many medical journals are the descriptions of the soldier's heart, or effort syndrome, or cardiac neurosis, or neurocirculatory asthenia—call it what you will. For definition of this condition, effort syndrome, with which the diagnosis of heart disease is so often confused, I refer to the excellent writings of Thomas Lewis¹ and Alfred Cohn.² Lewis writes as follows:

When a healthy man takes exercise, and this exercise is sufficiently stressful or prolonged, he becomes aware at the time of the effort, or after it has ceased, of certain symptoms, and he presents certain physical signs. The most notable of his symptoms is breathlessness, a symptom which comes during the exercise and continues with diminishing intensity for a variable period afterward. During the exercise, consciousness of the heart beat may come; giddiness or actual faintness or fatigue may be added. At the cessation of the

exercise, aching of the limbs, tremulousness and exhaustion are experienced; at a later period, stiffness of the muscles, a feeling of lassitude and sometimes actual malaise and tremulousness are noticed. In cases of extreme effort, pain over the precordial region, at first aching but exceptionally more violent and widespread, may be felt. During the period of exercise the heart rate and blood pressure are raised; the alae nasi are dilated, the accessory muscles of respiration are brought into action to increase the tidal flow of air. To these physiological symptoms and signs briefly described as a group I apply the term *physiological syndrome of effort*. . . . The difference in symptomatology which exists between health and this form of ill health is largely a difference in degree; the gage is the amount of work which, performed in a given space of time, will provoke the symptoms. Symptoms produced in normal subjects by excessive work are produced in the patients by lesser amounts; the smaller amount of work required, the more severe the malady. Naturally, there is no sharp line of division; there is in a large group of patients a perfect grading from the healthy man to him who is seriously unwell. We are traveling in the borderland between health and disease. This point of view has its value; it directs investigation toward the normal reactions of the body to exercise and to the corresponding reactions in disease; it brings us to inquire into the reserves of some of the most important bodily functions, and into the manner in which these reserves are reduced.

He also states that:

One of the largest groups of effort syndrome is that of constitutional weakness, nervous or physical or both. In this group are many who show incomplete or imperfect development. To it belong many undersized men, many with flat or elongated chests and instances of infantilism; to the same group belong many with family histories tainted by insanity or epilepsy, and those who in childhood were nervous weaklings, bed-wetters, somnambulists, etc.

The term "effort syndrome" is incomplete, in that it does not express the reaction of these patients to excitement. Excitement alone may produce the same symptoms as effort.

Since my return to civil life, I have noticed a group of cases, particularly in young women, which had been diagnosed as heart disease, sometimes for years, not infrequently as mitral stenosis, and which I feel were no more heart disease than were cases of effort syndrome encountered in soldiers during the war. In the Massachusetts General Hospital I have seen twelve such cases in the past six or eight weeks. The importance of this matter is obvious. If these patients have not heart disease—and the evidence is against their having heart disease—reassurance and treatment of their nervousness are the important therapeutic measures. Much worry has been occasioned and much time has been lost for some of these people as the result of the inaccurate diagnosis in the past. Since young women, as compared with young men, are generally more subject to exhaustion or irritability of the nervous system, it is likely that they more often develop the effort syndrome. It is not, however, merely in young women that we have seen the incorrect diagnosis of mitral disease.

Other conditions besides effort syndrome which, because of the symptomatology, may simulate heart disease are hyperthyroidism and infectious diseases.

In the past, great stress has been laid on the symptoms ordinarily found in serious heart disease, dyspnea, palpitation, precordial pain and tenderness, but more and more it has become obvious that the same symptoms may occur when the heart is apparently sound and when the condition is that of effort syndrome or

2. Cohn, Alfred: *The Cardiac Phase of the War Neuroses*, Am. J. Sc. 158: 453, 1919.

nervousness. As the patient's attention is called to his or her heart, the symptoms tend to become more and more aggravated. In old people these symptoms are probably much more significant of heart trouble, but in young people who are nervous and in whom no signs of heart disease can be found, the presence of dyspnea and palpitation and even precordial pain should be regarded as very uncertain evidence of heart disease.

To which of the symptoms and signs must we pay especial heed in the differential diagnosis between effort syndrome and early or slight actual heart involvement? In the first place, a past history of rheumatic fever is certainly important and tends to support a diagnosis of heart disease. On the other hand, a familial or personal history of nervousness or nervous prostration is much more in support of the diagnosis of effort syndrome. The symptoms of dyspnea, palpitation, pain and tenderness are insufficient for differential diagnosis. Lewis¹ states that "breathlessness of purely cardiac origin is always accompanied by general cyanosis—slight, moderate or extreme."

Some physicians have paid much attention to tachycardia, extrasystoles and systolic murmurs in diagnosing heart disease. Here again we may be led astray, since all these conditions are apt to be found in people with the effort syndrome. A recent discussion by Lewis³ covers these points.

Positive evidence of heart disease on physical examination includes any of the following:

1. Definite cardiac enlargement, to be determined, if in doubt, by teleroentgenography or orthodiagraphy.

2. The presence of a diastolic murmur. If one suspects the presence of a presystolic murmur and cannot be sure of it, it is usually wiser to consider it as not existing. Such a patient should be checked up by later examination. The exercise test used to bring out a presystolic murmur also causes in cases of effort syndrome the first sound to become so forcible and tumultuous that a mistaken diagnosis of mitral stenosis may sometimes be made from the character of this sound.

3. A systolic murmur at the apex, if very loud, and especially if it masks the first sound, usually means evidence of actual involvement of the mitral valve. The slower the pulse the more important is this murmur. Transmission of the systolic murmur to the axilla and back depends on the intensity of the murmur: the more intense the murmur the further it is transmitted, and the more likely it is to be evidence of organic valve disease. Therefore, transmitted murmurs are more apt to be evidence of true mitral disease, but not necessarily so.

- A very loud systolic murmur at the base, with thrill, indicates the presence of stenosis of the pulmonary valve or of the aortic valve.

4. The presence of serious arrhythmia, that is, heart-block or auricular fibrillation, if not the result of digitalis.

5. Congestion of the veins of the neck.

6. Enlargement of the liver. Edema of the feet and legs, or, if a patient is in bed, of the sacral region; ascites and hydrothorax, and edema of the lungs.

7. Cyanosis.

The presence of very severe anginal pain is in favor of organic heart disease. The presence of extreme nervousness, tremor, sweating, and other vasomotor phenomena favors the diagnosis of effort syndrome. Occasionally one finds a combination of the two conditions which may give rise to a good deal of difficulty in diagnosis.

Meredith⁴ has recently found among 2,000 young women in college and in clerical and factory work, 193 who had been told by physicians that they had heart trouble, usually valvular, and had been advised to work as little as possible and to rest all they could. On examination, she failed to find in these 193 women evidence of organic heart disease, but she did find functional heart disturbance which she ascribed to myocardial subdevelopment, but which, from her description of the symptoms and signs, fits very well in the effort syndrome class. These women should, of course, have their attention distracted from the heart, and their life occupied with work and play which will not be too strenuous for them. Neuhof⁵ has recently discussed the irritable heart as found in general practice. He considers the vasomotor symptoms more pronounced in civilian cases than in soldiers. He says, "The fundamental cause of the cardiac neurosis with its various manifestations, seems due to hyperexcitation of the sympathetic nervous system."

There is one further point to which I should like to call attention and that is, that even when the heart is damaged and a diagnosis of slight involvement can accurately be made, the life of the individual should not be too closely restricted or the patient too much alarmed over the abnormal heart finding. It has been shown by Mackenzie and others that people with slight heart disease may live active, useful lives without difficulty.

REPORT OF CASE

A case is herewith reported in order to illustrate the differential diagnosis between heart disease and effort syndrome.

History.—M. H., woman, aged 28, single, machine operator at a box factory, reported that she had always felt run-down and had become very tired operating a heavy machine, which she had done for the last eight years. Two years before, after a hard day, she fainted and had palpitation. No more fainting attacks had occurred, but there had often been palpitation, exhaustion and dyspnea, especially after exertion or excitement. Needle-like precordial pains occurred with the palpitation, beginning with the first attack two years before. The pain never extended to the back or arms. There was no history of fever, loss of weight, cough or hemoptysis. The palpitation consisted of pounding of the heart, at times irregular, like a double beat felt in the chest and head. Running for a car would sometimes start an attack of palpitation. The patient had always been easily excited; was very nervous and "trembly"; and this condition had grown gradually worse. Two years ago she went to a physician and was told she had "bowel trouble, not heart trouble." She had not worked for the past three months, and had been in bed off and on. She felt more exhausted and her heart seemed weaker in the morning than in the evening.

There was no history of infection of the rheumatic type.

The father died young; the mother was living, but was very nervous.

Physical Examination.—There was no cyanosis. The thyroid gland was palpable but not definitely enlarged. No exophthalmos. A slight tremor was noted. Knee jerks were very active. No cardiac enlargement could be made out; rhythm was regular at rate of 98; there was a soft systolic murmur at the base, the first sound at the apex was very loud and accentuated by exercise; no diastolic murmur could be heard; the heart action was forcible. The pulse was normal. Blood pressure readings were 110 systolic and 80 diastolic. The Wassermann test was negative. The blood findings were: hemoglobin, 75 per cent.; red blood cells, 4,600,000 per cubic millimeter.

4. Meredith, F. L.: Functional Heart Disturbances in Women, *Boston M. & S. J.* 181: 734 (Dec. 25) 1919.

5. Neuhof, S.: The Irritable Heart in General Practice, *Arch. Int. Med.* 24: 51 (July) 1919.

3. Lewis, Thomas: On Cardinal Principles in Cardiological Practice, *Brit. M. J.* 2: 621 (Nov. 15) 1919.

Diagnosis.—This case was diagnosed "double mitral disease," that is, mitral stenosis, because of the symptoms, the pounding heart action, and the suspicion of a presystolic murmur. The whole picture is that of nervousness with the effort syndrome.

COMMENT

The differential diagnosis in young people between heart disease and nervousness, or the so-called "effort syndrome," is in need of great emphasis at the present time. This is particularly true in the case of young women, who are probably more susceptible in civil life to the condition than are young men.

RUPTURED ECTOPIC PREGNANCY IN UTERINE CORNU

AFTER SALPINGECTOMY FOR PREVIOUS
TUBAL PREGNANCY *

JOHN DOUGLAS, M.D.

NEW YORK

REPORT OF CASE

A woman, aged 30, admitted to St. Luke's Hospital in December, 1916, had had a severe abdominal pain about four hours before admission, and had fainted. On admission, she was in shock, and was bathed in cold perspiration; the pulse was almost imperceptible, but could be counted at the apex with the stethoscope, the heart rate being 152 a minute. The abdomen showed a boardlike rigidity. There was a mass in the left fornix, and as the patient had skipped her last menstrual period a diagnosis of ruptured ectopic pregnancy was made. As her condition was becoming worse rather than better, she was operated on without delay.

Hypodermoclysis needles were inserted under both breasts before the administration of nitrous oxid gas. A midline incision was rapidly made. The abdomen was found full of blood. The bleeding ruptured left tube, together with the ovary, was removed. At the same time an assistant was removing a liter of blood from the patient's husband, and this was given to the patient by the citrate method, without waiting for the usual grouping tests, in view of the patient's condition. She made an uneventful recovery.

More than two years later, March 6, 1919, the patient had a similar attack except that the symptoms were not so severe as in the previous attack. By vaginal examination, marked tenderness could be demonstrated in both fornices, and the right ovary could be felt somewhat enlarged. As she was twelve days past her menstrual period, all other periods in the past two years being regular, it was believed that she had a ruptured pregnancy in the remaining right tube.

At operation the abdomen was again found to contain a considerable quantity of blood, with bright red blood coming up from the pelvis. The right tube and ovary were brought up into the wound, and except for a large corpus luteum cyst in the ovary, were found normal. It was then discovered that at the left cornu of the uterus, where the tube had been removed at the operation previously, there was a ragged, raw, bleeding area, which evidently represented a ruptured ectopic pregnancy. No ovum was found, but on the edge of the raw area was a small peritoneal cyst filled with clear fluid and lined with flattened epithelium. An effort was made to introduce a probe through this area, but no communication with the cavity of the uterus could be demonstrated. The raw area was closed by sutures through the uterine tissue.

COMMENT

Ectopic pregnancy occurring in a remaining tube, after salpingectomy in the other side, is not an uncommon occurrence. Rongy,¹ in an article on ectopic ges-

tation based on a study of 100 cases, reported twelve cases of repeated ectopic pregnancies included in this series. He quotes Smith and Rabinowitz, who have made a study of 2,998 cases of ectopic gestation, in which there were 113 cases of recurrent ectopic pregnancy, or 3.8 per cent. In all probability, as suggested in the article mentioned, if the subsequent history of these primary cases could be followed for a sufficient time, this percentage would be larger. This brings up the question of the advisability of the suggestion, that, in a woman, who has borne three or more children, the danger of a repeated ectopic pregnancy be explained to the patient, with the idea of obtaining consent for the resection or ligation of the remaining tube at the time of operation for the ruptured ectopic gestation.

The case reported furnishes an interesting conjecture as to how the impregnation occurred. The first operation was done rapidly, as circumstances required. The tube was tied close to the uterine cornu and removed, no attempt being made to excise a wedge-shaped portion of the uterine cornu. At the second operation, all evidence as to whether a sufficient amount of stump had been left to allow an ostium to become patent again was removed by the rupture that had occurred.

The question remains, How did the fecundated ovum become attached to this point? Did it pass down the right tube and across the cavity of the uterus and attempt to enter the remains of the left tube, and if so should it not have been possible to find a communication with the uterine cavity with the probe? If this did not occur, it must have reached its point of attachment by means of the peritoneal cavity, in which case it is of considerable interest to conjecture where it became fecundated and how or why it became attached to the remaining stump of the resected tube.

568 Park Avenue.

ACUTE RESPIRATORY DISEASE CARRIERS*

LESLEY H. SPOONER, M.D.

BOSTON

The prevalence of respiratory infection, especially among young adults, has been the subject of many statistical reports. Vaughan and Palmer¹ have shown that for the six winter months of 1915, 43 per cent. of the deaths occurring in the United States between the ages of 20 and 29 were due to this cause. The interest aroused in the subject was increased on mobilization of our troops during the winter months of 1917 and 1918. Covering a similar period, 77 per cent. of the deaths among the troops of approximately the same age as quoted above resulted from respiratory infection.

In this group it was shown that the organisms which I shall discuss were of great importance. Pneumonia was twelve times more prevalent in the army than in civil life, meningitis forty-five times, and diphtheria two times. Although the etiologic factors of measles and scarlet fever remain unknown, the streptococcus is well known as an organism of importance in the production of dangerous complications and sequelae. The same report states that measles was nineteen and

1. Rongy, A. J.: *Am. J. Obst.* 77:86 (Jan.) 1918.

* Read before the New England Oto-Laryngological Association, Nov. 19, 1919.

1. Vaughan and Palmer: Report from Section of Communicable Diseases, Division of Sanitation, Surgeon-General's Office.

scarlet fever six times more prevalent in the military than in the civil population.

Since the discovery by Pasteur that the pneumococcus could be cultivated from the saliva of healthy persons, various other organisms, the etiologic factors of respiratory infection, have been demonstrated on the normal mucous membrane. The significance of the presence of these bacteria was not realized at first, except to throw doubt on the etiology of certain of these diseases. Later, however, it became well recognized that persons harboring such organisms were factors in the spread of infectious diseases. To such individuals has been applied the term "carriers."

In many instances the organism may be only temporarily present, and in others it may be a constant inhabitant of the respiratory tract. This division of carriers into the transient, and the persistent or chronic groups, will be considered later. The most important classification seems to me to depend on the manner in which the organisms become planted on the mucous membrane of the carrier. It has long been known that the presence of any of these bacteria was no proof of previous infection by that organism. To this group I apply the term the "healthy carrier." Cole has shown that after infection by the pneumococcus, from 12 to 13 per cent. of those infected with Types I and II remain as bearers of those specific cocci. A similar condition follows infection by *Bacillus diphtheriae* and the meningococcus. This group will be referred to as the "diseased carrier." Still another consideration is the virulence of the organism isolated from the carrier. This appears to be of less significance than the latter, since the temporarily avirulent organism may, when implanted on fresh soil, regain its lost virulence.

In this paper I shall consider the four most important organisms that are the etiologic factors of acute respiratory infection. These are the pneumococcus, *Bacillus diphtheriae*, the meningococcus, and the streptococcus.

PNEUMOCOCCUS

Cole,² after an intensive study at the Rockefeller Hospital on acute lobar pneumonia, points out that the four types of the pneumococcus may be reclassified according to their occurrence in carriers into two general subdivisions: the truly parasitic and the primarily saprophytic pneumococci. Types I and II fall into the former division, Types III and IV into the latter. He was able to isolate from a series of 297 healthy persons, not exposed to the disease nor giving history of respiratory infection, a member of the parasitic group only once—a percentage of 0.33. On the other hand, the same series showed the saprophytic group³ in 115 persons, a percentage of 39. Following lobar pneumonia caused by the Type I pneumococcus, on the other hand, he succeeded in recovering that organism late in convalescence in 13.1 per cent., and the Type II organism following that specific infection in 12.1 per cent. It is not to be inferred that Types III and IV are essentially saprophytic organisms, since together I found them as etiologic factors in approximately 63 per cent. of more than 1,300 cases of lobar pneumonia which I studied. The fact remains that of the truly parasitic group which was responsible for 37 per cent. of my cases, the "healthy carrier" was essentially unknown.

2. Avery, Chickering, Cole and Dochez: Monograph 7, Rockefeller Institute for Medical Research, 1917.

3. The saprophytic group included, in addition to Types III and IV, the atypical Type II organisms, which Cole has shown are more closely allied to those groups than to the typical Type II.

In a study of the correlation of the types of pneumococci obtained from the circulating blood and the sputum in lobar pneumonia, I was able to demonstrate certain changes in the respiratory flora which further suggest the separation of the pneumococcus into parasitic and saprophytic groups. In several instances, the types recovered from the sputum in the later stages of the disease changed from the parasitic group, which had earlier been found in both blood and sputum, to the saprophytic group. From this fact it seems at least suggestive that in Types III and IV there are certain harmless strains; while other members, presenting the same serologic reaction, are frequent factors in the production of pneumonia. It is fair to assume that the convalescent pneumonia patient is a far greater source of danger, in regard to the spread of infection, than the healthy person, even though the latter is a bearer of the pneumococcus.

Epidemiologic studies of pneumonia in our large camps during the recent war have shown most interesting outbreaks of the various types of the disease. I was fortunate enough to be able to observe such waves of infection at Camp Devens. In the winter and spring of 1917 and 1918, the infection was caused largely by Type IV. This was followed by an outbreak of Type I, especially among two battalions of negroes who had recently arrived from Florida. This was succeeded by a preponderance of Type II cases, which was again followed by Type IV. During this period the usual sporadic cases were found, showing the classical percentage of types. These waves of infection, or small epidemics, can be explained best by infection from the individual in the early stages of pneumonia or from the diseased carrier during late convalescence.

The presence of the pneumococcus in the sinuses, incident to recent acute or present subacute infection, is doubtless of great importance in connection with the spread of disease; but my experience on the subject is too limited to warrant any conclusion.

BACILLUS DIPHTHERIAE

The Klebs-Loeffler bacillus, like the pneumococcus, has long been recognized as a possible inhabitant of the healthy throat. During a period of ten months, my laboratory at Camp Devens examined 3,800 contacts with cases of diphtheria. On the diagnosis by the laboratory of a case of that disease, all members of the patient's company were brought to the laboratory and cultures made at once on Loeffler's blood serum.

Of the 3,800 persons examined, 140 positive carriers were detected, a percentage of 3.7. In a paper published last year⁴ I said:

The healthy carrier may, according to the experience of this laboratory, be divided into two classes, the transient and the persistent carriers. In the search for diphtheria carriers it was necessary to rely for diagnosis on the microscopic morphology and staining reaction of the organisms and the relative number of such bacilli. Limits of time, personnel and material prevented more elaborate cultural differentiation, animal inoculation, etc. In order to safeguard as far as practicable against error in this report, the following requisites for diagnosis were insisted on:

First, the suspected type of organism must be present in at least moderate number in the preparation; second, the diagnosis must be made independently by three trained members of the staff or personnel.

4. Spooner, L. H.: The Base Hospital Laboratory, Mil. Surgeon 44:55 (Jan.) 1919.

It seems wise to make this detailed technical statement in order that the results of this investigation may be taken at their proper value.

The daily examination of cultures from the throats of the carriers yielded interesting results. Of the 140, 121, or 86 per cent., showed negative cultures within five days of isolation. To this large group I apply the name "transient carrier." Fourteen, or 10 per cent., showed organisms present between six and fifteen days following isolation. These might be classified as an intermediate group. Five, or 4 per cent., showed cultures positive over a period longer than fifteen days, the actual time being seventeen, twenty-one, sixty-two, seventy-five⁵ and eighty-five days, respectively. From these figures it may be concluded that 3.7 per cent. of contacts were found to be carriers, and that of the latter, only 14 per cent. were of practical epidemiologic importance, since the presence of bacilli in the throat of the remaining 86 per cent. was so transient. In other words, only 0.5 per cent. of those examined were significant carriers, harboring bacilli longer than five days, and only 0.1 per cent. were proved to be true chronic carriers. The transient carrier has an added significance in time of epidemic, although his importance in the dissemination of disease is not considerable under ordinary conditions.

The process of disinfection of all but the chronic carrier was too simple to warrant more than passing note. It consisted of rest, fresh air, house diet, and generally no local treatment, although occasionally bland mouth washes and gargles were employed, care being taken that their use did not interfere with the cultural results. The release from quarantine and the negative findings referred to in these statistics were gaged by three negative cultures, from the nose and throat, taken on successive days.

The "diseased carrier," the convalescent from diphtheria, presented a very different laboratory picture. In this case the persistence of positive cultures was always pronounced, and more radical steps, such as tonsillectomy and nasal operations, were often resorted to. These were frequently followed by a disappearance of the organism, which was unfortunately not always permanent. One case in particular deserves a brief note:

On admission, a soldier presented moderate constitutional symptoms and a small membrane on the left tonsil. Cultures from the latter revealed *B. diphtheriae*. After appropriate serum therapy, the constitutional reaction and the membrane disappeared, but the bacilli remained. Daily cultures from each tonsil, each nostril and the postnasal space showed negative results in every instance, save that of the left tonsil, cultures from which remained positive for from six to eight weeks. At that time the tonsil was removed in the usual manner. During his convalescence from this operation, negative cultures were obtained from all sources. After a week, however, the left tonsillar fossa showed positive cultures, which continued with as much persistence as before the operation. At last the patient was discharged from the hospital on the grounds of the nonvirulence of the organism.

From these observations I conclude that:

1. The chronic healthy diphtheria carrier is very rare.
2. Although the sterilization of his mucous membrane is difficult, it is easier than that of the chronic disease carrier.

3. He and his fellow, suffering from the early stages of acute infection, are the potent factors in the spread of this disease.

MENINGOCOCCUS

When Weichselbaum identified the meningococcus in the spinal fluid in epidemic cerebrospinal meningitis, it was supposed that the infection was restricted to the meninges. At present it is recognized as a septicemia. The organism gains entrance through the upper respiratory tract, and may be found in the postnasal space of both the healthy carrier and the person sick with the disease.

During the recent war the marked increase in this form of meningitis was the cause of a considerable disquietude in the Office of the Surgeon-General. As a natural consequence, the search for meningococcus carriers was carried out in a most elaborate and painstaking manner on all disease contacts. My experience revealed a low percentage of healthy carriers, 1.3 per cent. of 3,647 being detected, although the percentage of a limited group ran to 6.9 per cent. of 116 who had been in most intimate contact with infected subjects. It is, of course, impossible to state whether these carriers were responsible for the infection, or whether, as seems more likely, they became carriers because of close exposure to the disease.

In the South this form of meningitis is more prevalent than in this latitude. As Vaughan and Palmer have shown that the soil from which troops were drawn governs the prevalence of infectious disease, it follows that the Southern camps presented a high meningitis morbidity. At the same time the percentage of healthy carriers detected in those cantonments was correspondingly high. Here again it is difficult to assign any epidemiologic significance to the carrier.

We are confronted with a problem, which, technical though it may be, has a marked bearing on the interpretation of all results on this work. The cultivation of the meningococcus is difficult even from spinal fluid, but this difficulty is greatly increased when the organism is mixed with the usual saprophytic bacteria of the postnasal space. This tends to reduce the number of positive findings. On the other hand, it often rendered necessary the diagnosis of carriers from a relatively small number of organisms. The inevitable result is the diagnosis as carriers of many who harbor what might reasonably be considered an insignificant number of meningococci. This point is strengthened by a consideration of the response to treatment.

The usual method of disinfection was through the use of postnasal sprays of dichloramin-T. In the case of all our healthy carriers, the results of this treatment were most striking. The regulation for release consisted of three consecutive negative cultures taken at three-day intervals. In the case of the healthy carrier, the maximum period of isolation was twelve days.⁶

As I have stated above, the clinical meningitis patient is also a carrier of the organism in the postnasal space during the disease and convalescence. These diseased carriers were disinfected with greater difficulty. The maximum period of isolation was forty-three days.

The group of chronic healthy carriers, as in the case of diphtheria, is a small one. None typical of this type were detected among 3,647 contacts. They present two

5. At the time of preparation of the paper referred to in Note 4, this patient was in the hospital showing positive cultures.

6. This excluded one carrier whose isolation lasted seventeen days. He should be classified in an intermediate group, since the original examination revealed an almost pure culture of the meningococcus. The latter characteristic belongs to the chronic type, although the period of isolation prevents him from being classified as such.

characteristics which differentiate them from the type that was identified in my laboratory. They harbor the meningococcus in almost pure culture, and defy the utmost measures of disinfection. I observed such a group, consisting of perhaps a dozen men drawn from our entire army, when visiting the Rockefeller Hospital in May, 1918. From these observations it seems fair to conclude that the chronic healthy carrier of the meningococcus is rare, and that the important bearer of infection is the diseased carrier.

During the epidemic of influenza which swept Camp Devens during the latter part of September and October, 1918, a peculiar outbreak of epidemic cerebrospinal meningitis took place. In less than four weeks, twenty-two cases of this disease had developed in a camp that had shown only twenty cases during the ten months from October, 1917, to August, 1918. The most striking element in this outbreak lay in the fact that fourteen of the twenty-two patients (64 per cent.) had been confined in the hospital with influenza five days or more prior to manifestation of the earliest symptoms of meningitis. Twelve (55 per cent.) had been patients for nine days or more before onset of this infection.

The following facts were brought out after an intensive study of the situation: The twenty-two cases represented eighteen separate camp organizations, which were in no way in close contact with one another. In spite of the crowded condition of the camp, in only three instances did multiple infection exist. In none of these could camp contact be satisfactorily demonstrated to an extent warranting any epidemiologic conclusions.

Two cases arose in A Company, 212th Engineers; of these one had been in the hospital ten and the second thirteen days prior to manifestation of symptoms. Of the two cases in the 31st Company, Depot Brigade, one had been confined to the hospital five, the second, twenty-three days. In the 14th Company, Depot Brigade, in which three cases developed, one was admitted sick with the disease; the second had been confined for nine, and the third for thirteen days. A comparison between the dates of manifestation of symptoms and of admission to the hospital shows that in the case of only one organization—the 212th Engineers—could the patients have been in personal contact within at least one week prior to onset of symptoms.

A study of the distribution of cases throughout the hospital shows that among those who evidently had developed the disease within the hospital, no two cases were found in the same ward. The frequent change of patients from ward to ward during the stress of the epidemic did not alter this unique record. Of the medical staff, hospital personnel, and nurses in those sixteen wards, as well as of the patients in contact with the case, cultures were taken with the utmost care. Of 586 contacts only twelve, or 2 per cent., were found to be healthy carriers. Similar cultures taken from the possible camp contacts showed nineteen carriers out of 1,061 examined, a percentage of 1.8. It is of interest to note that in the 14th Company, Depot Brigade, to which organization three patients belonged, no carriers were discovered among 219 examined.

Since no appreciable increase in the number of carriers was found among hospital contacts and in the organizations to which these cases belonged, and in fact since in the one to which were attached the largest

number, none were discovered; and as there was a wide distribution of cases through the camp as well as in the hospital, and such a large number developed the disease in the hospital after a lapse of time generally accepted as the incubation period of meningitis, it seems reasonable to consider these cases as possible autoinfections of the carrier. Although no absolute proof of this point has been produced, it seems rational to consider that these persons, whose vitality had been lowered by an attack of influenza, yielded in this manner to infection with the meningococcus. I will add that I have the informal statement from the Office of the Surgeon-General that such an outbreak took place in three other base hospitals in this country.

STREPTOCOCCUS

In civil life the streptococcus is an important factor in the production of septic sore throat, septicemia and more localized surgical infections. Its rôle in connection with pneumonia should not be neglected. In the army, however, it was found to be one of the most dreaded of infectious organisms. Bronchopneumonia either due to the streptococcus in the form of primary infection, or secondary to measles, with the resulting empyema and pericarditis, was responsible for the highest mortality in Southern camps. Primary and secondary infection of wounds by this organism was also of utmost importance.

The regional distribution of the streptococcus was fully as striking as in the case of the meningococcus.

Although many strains of the organism have been isolated, *Streptococcus hemolyticus* was almost universally found in connection with respiratory, as well as with wound, infection.

In the spring of 1918, a considerable number of cases of postmeasles streptococcus pneumonia were reported through my laboratory. This organism was also frequently demonstrated in postpneumonic empyema during that period and throughout the summer. Following the influenza epidemic, even larger proportions of the postpneumonic empyemas showed this organism, always in the rôle of a secondary invader. Toward the close of 1918, in a few returned wounded soldiers the organism was demonstrated in chronic sinuses and areas of bone destruction. With these exceptions, infection by *Streptococcus hemolyticus* was relatively rare throughout Camp Devens during the first fifteen months of its existence.

This preliminary statement is of importance in the consideration of my investigation on suspected carriers of this organism, which, it must be borne in mind, was terminated before the influenza epidemic or the return of wounded troops, noted above.

During the winter of 1917-1918, cultures were taken of 100 Medical Reserve Corps officers stationed at the base hospital. Cotton swabs were applied to the tonsils, and with this material the water of condensation of Loeffler's blood serum was impregnated. Diagnosis was made by microscopic morphology. In this series, 60 per cent. were found to be streptococcus carriers. A similar investigation on the nurses at the same hospital revealed 68 per cent. of sixty examined. A smaller group of regimental surgeons stationed throughout the camp was next investigated by the same methods. These showed only 5 per cent. of healthy carriers. Whether the marked difference resulted from the nature of the lives led by these groups, or whether

the hospital environment played a rôle in the production of carriers, it is difficult to decide. The former seems to me the more rational solution.

As it was realized that the technic was faulty, the next series was thus investigated: Swabs were planted directly on blood agar plates,⁷ and after twenty-four hours' incubation the microscopic morphology of typical hemolytic colonies was studied. This series covered 140 officers, about 75 per cent. of whom were included in the first investigation. The same process was repeated twice at three to four week intervals. The migratory life of the army officer prevented the completion of observation in all the group. This incompleteness tended to lower the percentage, which I believe would have been even more striking had the work been performed on a stationary body.

Of 140 officers of whom cultures were taken, 83 per cent. were positive on at least one examination; 25 per cent. showed *Streptococcus hemolyticus* in appreciable numbers on three or more trials, and only 17 per cent. were consistently negative. These figures indicate that the transient streptococcus carrier is very common and that the persistent carrier—I believe had my investigation been carried out over a longer period the term chronic carrier would have been appropriate—is also common.

When these facts are considered in the light of the scarcity of primary streptococcus disease at this hospital and the absence during their entire residence at that post of such infection among the Medical Corps officers, the importance of the streptococcus carrier, as an etiologic factor in the origin and spread of that infection, becomes parallel to that of the pneumococcus carrier. Another analogy to that organism lies in the recent work on streptococcus grouping, which will probably separate these organisms into parasitic and saprophytic groups similar to those of the pneumococcus.

It is my opinion that in the case of the streptococcus, healthy and diseased carriers bear the same relation to the health of the community as exists with the other organisms just discussed.

CONCLUSIONS

1. Acute respiratory disease is at present the greatest menace to the youth of our country.
2. It is more serious in the army than in civil life.
3. The transient healthy carrier is more common than should be expected from the incidence of the specific disease.
4. This transient quality is shown by the disappearance of the organism without treatment.
5. The chronic healthy carrier is rare, except in the case of the "saprophytic pneumococcus" of Cole, in which many of the organisms may be nonpathogenic, and with *Streptococcus hemolyticus*, in which a similar condition may well exist.
6. The potent factors in the spread of these diseases rest in this small group of chronic healthy carriers and the diseased carrier.
7. The latter, during the prodromal stages of disease and convalescence, is of by far the greatest importance.
8. They respond to attempts at disinfection even less satisfactorily than do the chronic healthy carriers.

ELECTRICAL STIMULATION OF PERIPHERAL NERVES EXPOSED AT OPERATION

SURGICAL VALUE

WALTER M. KRAUS, A.M., M.D.

NEW YORK

AND

SAMUEL D. INGHAM, M.D.

PHILADELPHIA

The occurrence during the war of large numbers of nerve lesions of traumatic origin has stimulated the investigation of nerve function by various methods, among which that of electrical stimulation is of recognized importance. Operations for the correction of these lesions have furnished the opportunity for the direct stimulation of exposed nerve trunks, pathologic and normal, by which means extremely important information may be gained. This paper is based on such observations in a series of seventy-three cases in which operation was performed in the service of Lieut.-Col. C. H. Frazier at U. S. Army General Hospital No. 11, Cape May, N. J., and U. S. Army General Hospital No. 41, Fox Hills, N. Y., and aims at presenting general conclusions and such other data as may be of interest to the surgeon. The case reports, with more detailed anatomic and theoretical consideration, will be embodied in another paper.

TECHNIC

As soon as nerves are freed at operation, those of the leg are oriented at a point distal to the lesion by a black silk thread passed through the sheath on their posterior aspect, and proximal to the lesion by a white thread similarly placed. The arm nerves are oriented in the same way on the anterior aspect. This permits proper orientation for stimulation, suture and pathologic examination.

The stimulating electrode (Fig. 1) used was bipolar and was devised by one of us (W. M. K.) following the principle of the French investigator, Henri Meige. It is rather simple. Two strands of No. 2 copper wire about 2 yards long are strung with small glass beads for insulation. The two strings of beads are placed in a glass tube, 8 inches long, whose edges are well rounded, and are held in position by nonvulcanized rubber. Another modification of the electrode is as follows: At a point, about 1½ inches from the handle end of the tube, a slight indenture is made by drawing the tube out a bit. The beaded wires are drawn toward the stimulating end and a rubber band is placed over them at the indenture, thus holding them in place. The beaded wires are then allowed to trail off in their original direction (Fig. 1). The stimulating ends of the electrode are twisted back on themselves, thus making a loop. This avoids trauma to the nerves. This electrode may be readily sterilized. The battery used was the Harvard inductorium, No. 20, made by the Harvard Inductorium Company, Boston (Fig. 2). The freed nerve is held by a glass rod with a curved end which permits it to rest as in a cradle. The strength of the current is best taken as that which will produce a minimal contraction in a neighboring muscle. This rarely fails to cause stimulation of the nerve. The stimulation should always be applied both below and above the lesion. Normal nerves require much less current than abnormal. The stimulating is done with

the electrodes placed longitudinally on the nerve—this to avoid diffusion as much as possible. The sequence is: posterior side, internal, anterior, external. The surgeon while stimulating calls out the aspect of the nerve he is working on, in order to avoid confusion. The muscles stimulated are observed by another man. In stimulating the arm nerves it is better to use the terms radial and ulnar than internal and external. It has been found valuable to have nerve maps in the

in estimating the degree of nerve injury and in facilitating operative procedure. It enables him easily and quickly to identify normal nerves, often a difficult matter otherwise, especially when the normal anatomic relations are disturbed by pathologic conditions. Again, direct electrical stimulation is the most dependable means of determining conductivity in motor nerves which have been injured but not interrupted, as in the case of compression.

Fig. 1.—Stimulating electrode.

Fig. 2.—Battery.

operating room for reference. The findings are directly recorded on circular charts.

VALUE OF THE METHOD TO THE SURGEON

The surgical aspects of this subject are of considerable importance, not only because of the increased accuracy of diagnosis and of surgical manipulation which a better knowledge of topography insures, but also because direct electrical stimulation of nerves exposed at operation is of material aid to the surgeon

ELECTRIC PHENOMENA

We are all familiar with the paradoxical phenomenon of Erb, most frequently found in compression palsy of the musculospiral nerve from the use of crutches. In this condition the nerve conducts impulses when it is stimulated through the skin below the area of compression, but this area acts as an area of decrement, and its muscles cannot be made to react when the nerve is stimulated through the skin above the point of compression. We have found that in some cases the nerve

and its muscles are quite unresponsive to electrical stimulation at all points through the skin, while direct stimulation of the nerve trunk at operation causes muscle reaction. We have also observed all of the conditions of Erb's reaction elicited by direct stimulation of the exposed nerve.

3. A phenomenon of difference between percutaneous and direct stimulation.

The explanation of the last mentioned phenomenon appears to be simple. The direct stimulation of an exposed nerve is stronger and less diffused, and suffices to overcome the decrement in conduction produced by

Summarizing the phenomena due to areas of decrement which we observed, we have:

1. Erb's indirect, or percutaneous, paradoxical phenomenon.

2. A direct paradoxical phenomenon, from stimulation of the nerve trunk.

the lesion, while stimulation through the skin does not.

The surgical importance of these reactions is obvious. Where conductivity can be demonstrated, nerves or portions of nerves can be conserved which might otherwise be considered as completely interrupted and consequently subjected to unnecessary operative resection

and suture. Finally, the free ends of nerves that have been completely interrupted can be identified in the recent stage of injury, that is, until secondary degeneration develops. In cases in which it is of interest to cut the fibers to some muscles, let us say the gastrocnemius and soleus group, as in Little's disease, or when a trans-

It serves as an indispensable guide to operative manipulations.

It is a means by which we may add to our all too scanty knowledge of peripheral nerve anatomy.

RESTORATION OF LOSS OF BONE

INCLUDING AN ANALYSIS OF THE FIRST HUNDRED CASES OF FRACTURE TREATED BY BONE GRAFT AT U. S. ARMY GENERAL HOSPITAL NO. 3, COLONIA, N. J.*

FRED H. ALBEE, M.D., Sc.D.

ASSISTED BY

ELMER P. WEIGEL, M.D.

NEW YORK

In the task of restoring loss of bone substance and function in the wide variety of traumatism resulting from the war, the plastic surgeon is confronted with a correspondingly varied array of mechanical problems. The recognition of the underlying biologic and physiologic significance of tissue growth and metabolism is a fundamental requirement in the successful treatment

Fig. 11.—Levels of stimulation of the main arm nerves and their branches.

plantation is desired, say of the triceps fibers into the circumflex nerve, it is essential to use electrodes.

RESULTS OF STIMULATION IN SEVENTY-THREE CASES

The results obtained have been combined for each nerve and are represented on the accompanying charts (Figs. 3, 4, 5, 6, 7, 8, 9 and 10). The black areas represent the responsive area on the circumference of the nerve, namely, the area in which faradization caused muscle contraction. The arrow in Figure 4 indicates that the fibers to the pronator radii teres muscle cross from the external aspect to the internal aspect of the median nerve on its anterior surface, the extent of the crossing being several inches in the midarm portion of the nerve. The absence of a black line to represent the position of the fibers for the tibialis posticus in Figure 9, and the location of the numbers throughout the circumference, indicate that we were unable to localize definitely the fibers to this muscle, but found them on all aspects of the nerve in different cases. This was the only exception to the rule that the fibers to a given muscle pursued a straight course from the plexus to the point of branching. The charts of the circumferential position of various bundles represent the results of stimulation at various levels (Figs. 11 and 12).

Fig. 12.—Levels of stimulation of the sciatic nerve and its branches.

CONCLUSION

Electrical stimulation at operation gives important information to the surgeon as to the location of nerves and their degree of abnormality due to injury.

Fig. 1.—Requisite apposition of bone layers of graft with respective parts of host bone. The graft is of sufficient length to extend well beyond the eburnated area of the host fragments, coming into generous contact with the healthy vascular marrow substance. The cross-section at E shows the eburnated plug of bone where, as a rule in pseudarthrosis, it closes the marrow cavity in the fractured ends. Here the gutter has been deepened sufficiently to receive the full amount of marrow of the graft, which is demonstrated (lower drawing and cross-section at D) in extensive contact with the marrow of the host fragments. The arrows on the marrow in the host fragments indicate the direction of blood supply to the graft from its principal normal source, namely, the marrow substance of the host. By the insertion of the inlay, with its full amount of marrow, a continuous marrow bridge is formed, extending from the healthy marrow of both host fragments through the gutter in the eburnated ends. This marrow bridge plays a most important rôle as conductor of blood vessels and osteogenic cells from one host fragment to the other. The cross-sections at D and E show also the cabinet-maker fit of the inlay graft with the host fragments, which not only affords mechanical fixation of parts, but also favors the stimulus to bone growth from frictional irritation, emphasized by Roux.

of these cases. The surgical repair of bone, and more particularly the use of the bone graft in cases of pseudarthrosis with or without bone loss, is based not only on the ultimate establishment of adequate fixation of the bone fragments, but also on the attainment of a proper environment for the nourishment of the graft. This entails the exact coaptation of parts of the graft to respective parts of the host bone; in other words, the adequate and extensive contact of all four corresponding bone layers, namely, periosteum, cortex, endosteum and marrow.

* Read before the Congress of the Italian Orthopedic Association, Bologna, Oct. 18, 1919.

MECHANICAL STRESS AND BONE GROWTH

Throughout his plastic work, both in civilian practice and army experience, the author has been greatly impressed with the striking influence exerted by mechanical stress on the growth and metabolism of bone. In cases of loss of substance of long duration,

Fig. 2 (Case 1).—Wound in which an officer, hit at Oureq River by fragments of a high explosive shell, lost about $3\frac{1}{2}$ inches of the upper third of the humerus, including the entire head. In this case, destruction of practically all the musculature of the shoulder rendered the patient incapable of shoulder motion.

in the radius, humerus or any long bone, the bone cortex has often become reduced to one-fifth its normal thickness, in fact, almost to eggshell consistency, largely owing to removal of the stimulus of mechanical stress. Such a condition is, of course, in direct sequence to the general physiologic law of bone growth; it is, in fact, a magnification of Wolff's law. If bone, whose nourishment and blood supply have not been greatly impaired, should suffer so materially as a result of loss of the stimulus of mechanical stress, how much greater must be the effect of the same inhibitory influences on any free bone graft whose blood supply and nourishment are not yet established.

A more suitable environment for successful bone growth is established by the cabinet-maker fit of the properly inserted inlay graft than by any other known technic. At the same time the biologic laws that obtain in the transplantation of all varieties of tissues are fulfilled, since corresponding tissue-layers are brought in apposition, thereby furnishing ideal conditions for the rapid and complete establishment of the blood supply. Under such conditions, Wolff's law of bone growth is given favorable opportunity to exert its influence on bone proliferation and on the adequate adjustment of the bone architecture. Moreover, by the inlay technic, the full influence of Roux's law of frictional irritation is ideally provided for, since extensive plane surfaces of the graft are brought into the closest proximity with equally extensive plane surfaces of the host fragments.

TECHNIC

In work on bone tissues, which easily dry on exposure to the air, operative speed is necessary; moreover, in the repair of bone that from lack of the stimulus afforded by mechanical stress has become almost eggshell-like in consistency, great delicacy of technic and operative speed are fundamental requirements in the difficult work of inserting the necessary inlay. It would be impossible to execute such accurate inlay technic by the former laborious methods with mallet and chisel, or osteotome. In work of this nature, in which the operating field is frequently limited, where fragility of bone may be a constant menace to success, and in which an accurate cabinet-maker fit of parts is indispensable, an electrically driven rotary twin-saw seems absolutely essential. In contradiction to a recent assertion, it is emphatically stated that the motor-saw, when properly used, does not heat nor glaze the bone. During various operations in the past few months, the author has made repeated attempts to determine whether heat was generated by the motor-saw when used properly, and if so, to what degree. In every instance it has been found that the most delicately adjusted thermometers have failed to register an increase in temperature, even to the fraction of a degree, when placed directly on the motor-saw or on the bone immediately following the withdrawal of the instrument.

Methods of Internal Fixation.—For the inlay graft, accurately cut and fitted by motor-saw technic, the fixation afforded by kangaroo sutures is adequate and preferable to that of all metal agents (such as plates, nails, screws or wire). Kangaroo tendon, from the standpoint of mechanical strength, absorbability and tolerance by the tissues, surpasses all known fixation agents. It remains in situ sufficiently long for the purpose of fixation, and begins to be absorbed within forty days. Moreover, it is sufficiently elastic to allow the plane surfaces of an inlay graft to rub in a microscopic amount on the contiguous plane surfaces of the gutter of the host fragments, thus favoring the frictional irritation law of Roux.

Fig. 3 (Case 1).—Diagrammatic drawing (anterior view) to show the trusswork of tibial grafts in position and fixed with kangaroo tendon. Graft C is inlaid into the shaft of the humeral fragment at E, and mortised into the acromion process at D. Graft A is mortised into the glenoid body of the scapula at B, and attached by means of kangaroo tendon to Graft C at the point where the latter graft meets the end of the humeral fragment.

The practice of inserting metal plates (as recommended by some surgeons) is absolutely contraindicated in this work. The use of metal plates as the internal fixation agent not only robs the graft of mechanical stress, but an influence is thereby added

that contributes strongly toward the stirring up of old infections, if such remain in the tissues. Whereas, in tissues retaining only a slight amount of an original infection, a bone-graft operation speedily done with minimum trauma may bring satisfactory results, the introduction of a foreign body (such as a metal plate,

inch to six inches, and averaging about two inches; ten cases were for nonunion without loss of bone; the remaining four cases were for malunion. These cases are classified anatomically in Table 1.

SPECIAL METHODS

Some of the various methods of plastic repair employed in this series of fractures, more than four fifths of which involved loss of bone, are briefly described in the following groups of cases:

Restoration of Loss of Bone at Shoulder.—Owing to the exposure of the upper portion of the body in trench warfare, shoulder injuries, and particularly those involving the upper part of the humerus, have been frequent in the recent war. Through the rather extensive practice of certain surgeons at the front, more especially of the French, of removing large portions of bone at or near the shoulder-joint in such injuries as these, there has resulted a notable group of cases in which shoulder function is very nearly negligible, if not entirely destroyed, on account of the loss of bony framework over which the shoulder muscles might play. Of all surgical conditions, none pre-

Fig. 4 (Case 1).—The plastic operation in this case was performed four and one-half months after the patient was wounded and two months after the wound had healed. The roentgenogram demonstrates restoration of loss of bone by two tibial grafts, eight weeks after operation. Graft 1 was inlaid into the shaft of the humerus and mortised into the acromion process. Graft 2 was mortised into the glenoid body of the scapula and contacted with Graft 1 at the point where that graft met the humerus. During the union of the grafts the arm was held by a plaster-of-Paris shoulder spica in an elevated anterior posture and in such relation to the scapula that the powerful thoracic muscles controlling this bone might later move it and in a large measure restore its loss of function by causing the scapulohumeral motion to be compensatory for loss of shoulder motion.

nails or screws) adds a second devitalizing element, which, in the battle of tissues, may turn the scales unfavorably, with the result that infection again breaks out.

ANALYSIS OF CASES

A careful analysis of the first 100 cases of fracture treated by bone graft at U. S. Army General Hospital No. 3 during the period from July 15, 1918, to May 1, 1919, has yielded, it is believed, valuable data in regard to possibilities of treatment.

Of the 100 cases, seventy-nine involved bones in which injury resulted from high explosive shell, machine gun bullet, or shrapnel; seventeen were simple fractures of the long bones; the remaining four cases were compression fractures of the spinal vertebrae. All the simple fractures and the spine cases have been successfully treated, in that they have healed, in each instance, without infection, and have shown bone growth by roentgenographic examination within a reasonable period after transplantation of the graft. In every case of fracture of the long bones, function has been restored, while in the spine cases there has been an inhibition of symptoms.

Of the seventy-nine cases of fracture by projectiles, treated by bone graft, sixty-five, or 82 per cent., were for loss of substance varying in amount from one-half

Fig. 5 (Case 1).—Type of brace applied after removal of the plaster spica. This brace is so adjusted as to allow the arm to descend to a lower position than that maintained during the union of the grafts to scapula and humerus. This new position brings a slight amount of lateral stress on the grafts, thus stimulating their hypertrophy and development. It is obvious that this new posture causes the lower angle of the scapula to separate itself from the thoracic cage.

sents a picture of greater helplessness than a dangling arm from which the upper portion of the humerus is missing.

The high frequency of shoulder and forearm injuries is strikingly borne out in Table 1. In this series of seventy-nine cases of fracture by war projectiles, injury to bones of the upper extremities, as compared with those of the lower, has occurred in a ratio of nearly 4 to 1. Of the total number of cases of injury in the upper extremity, the humerus has been involved in fourteen instances, or more than 25 per cent. Cases of loss of substance in the humerus with loss of shoulder function have been classified in two groups, with respect to treatment:

Group 1. Restoration of Shoulder Motion and Function: This class consists of cases in which the

the patient can functionate satisfactorily without the upper end of the fibula. In these cases, whenever possible, the principal muscles of the shoulder, such as the pectoralis major, the supraspinatus and the subscapularis, are firmly affixed subperiosteally to the transplanted head and neck of the fibula.

Group 2. Shoulder Function Restored by Compensatory Scapulothoracic Motion (Figs. 2, 3, 4 and 5): This group includes cases in which, in addition to loss of bone, the musculature of the shoulder has been destroyed or severely injured to such a degree that one cannot hope to secure a return of shoulder-joint motion. In these cases, the loss of bone is restored by

Fig. 6 (continued).—Diagrammatic drawings 1' to 10' illustrate the author's technic in cases in which the end of the bone fragment (distal upper fragment in this case) is conical in shape and too small in diameter to receive the usual inlay graft which is shown in the proximal or lower fragment in these drawings. A wedge-shaped piece of cortex, *H*, is removed from the upper fragment. A split at the end of the wedge cavity may, or may not, be made by means of a thin osteotome, as shown at *I*. If the fragment is small in diameter and osteoporotic, as is usual in these cases, the bone may be bent on both sides of the cavity in the region of *I*, and the wedge cavity may be enlarged by driving a wedge-ended graft of larger diameter into it, as demonstrated in Step 9'. In Step 10', the wedge end of the graft is firmly immobilized in the distal or upper fragment by means of kangaroo tendon. The other end of the graft is then forced into the proximal fragment by means of a strong clamp at the same time that the graft is being levered endwise by means of a narrow osteotome, the object of this procedure being twofold; first, to restore as far as possible the length of the ulna, and secondly, to bring end stress on the graft as a stimulus to bone growth. These drawings were made with the distal fragment of the ulna uppermost because of the position of the arm during operation.

humerus has been destroyed, but the musculature has been sufficiently preserved to enable the surgeon to hope for a return of shoulder-joint motion and function, provided the bone be replaced. The author has restored motion and function in such cases by transplanting into the humeral fragment the head and upper end of the fibula to replace the upper portion of the humerus that has been destroyed. He has resorted to this operation many times in his civil practice, as well as in military work, and has invariably found that

ankylosing the humerus to the scapula by a truss-work of tibial grafts, usually two in number. During the union of the grafts, the arm is immobilized in an elevated anterior posture, and is held in such relation to the scapula that the powerful scapulothoracic muscles which control this bone may later move it. Thus, by causing the scapulothoracic motion to compensate for loss of shoulder motion of the arm, the lost motion of the arm and the shoulder is restored to a surprising degree.

In restoring loss of bone near joints, this technic has been employed: By means of an osteotome or chisel, a wedge-shaped mortise is made in the joint fragment and is extended under the capsule, and sometimes completely through to the joint cartilage, without damaging the joint. One end of the graft is driven into this wedge-shaped mortise. The other end of the graft is then inlaid into the long bone fragment by the usual inlay technic and is fixed with kangaroo tendon (Fig. 3).

Restoration of Long Bones.—Restoration of the shaft of the humerus, femur, tibia or any long, large bone has been accomplished by means of a graft inlaid by the author's usual inlay technic, as illustrated in Figure 6, in the larger fragment at *A, B, C* and *E*. On bones of the forearm, or on any bone of small diameter, or in cases in which a bone of large diameter has become conical-ended, as frequently occurs, the mode of repair which has been resorted to is designated, for purpose of description, as the "fishpole" technic (Fig. 6 *H, I* and *J*), since a similar method is employed by the artisan in mending a fishpole.

The influence of stress on the hypertrophy and metabolism of bone has been more strikingly illustrated in bone graft restoration of the shafts of long bones than in any similar class of work. However small the

cases is the plaster-of-Paris splint, applied with the utmost care and molded to the bony contours of the extremity. It should always include at least one joint above and one joint below the bone involved, with due attention given to position, which is of the greatest importance. By way of illustration, in cases of injury of the upper portion of the ulna, the arm should always be put up straight, never with the elbow flexed. In cases of injury at or near the lesser trochanter of the femur, the extremity should always be immobilized in a plaster spica with the thigh abducted and flexed.

Synthetic Grafting of Tissues in Construction of New Fingers.—In two cases of loss of

Fig. 8 (Case 2).—Loss of about 1½ inches of shaft of humerus.

the adjoining metacarpal bones as a result of high explosive shell and shrapnel wounds, the hands were completely helpless, so far as grasping and holding were concerned. In these cases, function has been restored to a great extent by the synthetic construction

Fig. 7 (Case 2).—Extreme laxity of left arm due to loss of substance in shaft of humerus as result of wound by machine-gun bullet at Cantigny. The plastic operation for restoration of bone and function in this case was performed seven months after injury and two months after wound had healed.

diameter of the graft, provided it be protected from fracture by external support and at the same time be allowed to withstand stress, it will eventually restore the lost bone in almost every anatomic particular, namely, in diameter, strength and external contour, as well as in respect to the internal architecture.

Immobilization in Extremity Work.—By making the most of all known mechanical joints and by the insertion of kangaroo tendon in such ways as to afford the best internal fixation, in conjunction with the most perfect external fixation by plaster-of-Paris dressings, the extremity being placed in various "positions of neutral muscle-pull," immobilization of the involved fragments has been found possible. Too great emphasis cannot be laid on the importance of putting absorbable ligatures in the skin, so that carefully applied plaster-of-Paris dressings need not be disturbed for a period of at least eight weeks after implantation of the graft. Plain catgut No. 0 or No. 1 with suture-holes puddled with tincture of iodine, serves admirably for this purpose. Chromic catgut, No. 0 or No. 1, is also suitable. The buried sutures in the soft parts should always be small in diameter and as limited in number as possible. The only adequate postoperative dressing in these

Fig. 9 (Case 2).—Method of immobilization of fractures of humerus. In this case the dressing was allowed to remain on for eight weeks.

of new digits. One of these cases is illustrated in Figures 12, 13 and 14. By providing an apposing surface for the thumb, the usefulness of the member has in each instance been restored.

In plastic work of this nature, which involves the transplantation of more than one kind of tissue, a two-step or multiple-step procedure is the only method whereby a successful sequence may be expected. It is essential, for example, in handling soft parts and bone (as in the construction of new fingers, in plastic repair

Fig. 10 (Case 2).—Tibial bone graft firmly united in position, ten weeks after plastic operation.

of the jaw, etc.) that skin and subcutaneous tissues be firmly united with the host-tissue and that circulation therewith be well established before implantation of bone. Ease of technic and the possibility of obtaining ample soft tissues and bone have also led the author to recommend strongly this type of operative procedure.

Repair of the Mandible.—Probably no branch of surgical repair presents greater difficulty of mechanical fitting and adjusting than in injury to the lower jaw, involving extensive loss of bone. Owing to the irregularity of contour of the jaw fragments, hardness of the bone and lack of anvil stability, such work demands an accuracy and precision of technic that can be secured only by the use of delicately adjusted motor tools, such as the author's tiny circular saws, burrs, drills, end-mills and the like.

Of primary importance is the cosmetic result. In many cases this depends entirely on the construction of a suitable graft framework over which to restore the contours of the face. Such a framework must secure the adequate fixation of the jaw fragments, as well as restoring, in many instances, loss of bone substance. In his plastic work on the jaw, the surgeon will do well to cooperate, so far as possible, with the prosthetic dentist in the application of the most efficient intradental splints. Use of such splints is, however, in many instances, impossible, owing to the extensive loss of teeth and of bone. In the latter cases, the sole means of fixation must be provided by the graft, which should be molded and firmly inlaid into each fragment, adequate in any emergency (such as removal of the dental splint on account of pressure necrosis, etc.) to supply the requisite fixation.

In other work, such as the restoration of the shafts of long bones, neck of femur, etc., the tibia has been found a satisfactory source from which to obtain the graft. In work on the jaw involving extensive bone loss, however, the tibial dimensions are not always sufficient to supply a graft of the necessary curve and size. In such an event, the side of the ilium, adjacent to the anterior superior spine, is the only bone, with the possible exception of the outer table of the skull, which is of adequate dimension to allow the proper modeling of the graft, which is done by means of motor-driven tools in a manner resembling the scroll-work of the cabinet-maker.

Relief of Compression Fractures of the Vertebrae.—The use of the bone graft as a means for relief of compression fractures of the vertebral bodies has afforded highly satisfactory results. On account of meager bone growth and inadequate bone repair around crushed vertebral bodies, and because of constant interference with bony union by the respiratory and voluntary motion, nature, unassisted, does not bring about the proper repair in these cases, even though efficient external means of immobilization be employed for months, and sometimes even for years. To supply the deficiency resulting from lack of bone repair, the bone graft offers a sure means of relief, and its indications in such cases are as definite as in any pathologic or traumatic conditions encountered. It is inserted into the spinous processes by precisely the same technic as has been devised by the author for the treatment of Pott's disease of the spine (Fig. 15).

Preoperative Treatment of Persistent Infection.—In our first series of 100 fracture cases treated by bone graft, we found that postoperative wound infections were more frequent in the last twenty-five cases than previously. However, these cases did not include in

Fig. 11 (Case 2).—Stability of arm from union of graft, ten weeks after operation. Such a posture was impossible before operation.

all instances those wounded at a later date, but rather those in which the primary wound took longer to heal; and the later infections, following the plastic operations, are attributed to a more severe primary infection and to a less complete immunization on the part of the patient.

At the time of the plastic operation, positive cultures were occasionally found in the scar tissue around the bone ends, and small sequestrums were removed from the bone fragments. Not all of these cases, however, showed infection following the operation. In those cases which did, the infection was usually of a mild, low-grade type, apparently owing to the attenuation of the infecting organism or to a partial previous immunization of the patient against that organism.

Fig. 12 (Case 3).—Left hand of an American soldier who lost completely the four fingers and adjoining metacarpal surface following a high explosive shell wound at Château-Thierry. One may note the absence of any apposing surface when the thumb is flexed, as a result of which nothing can be grasped or held.

The scar, on account of its low-grade tissue and its deficient blood supply, furnishes a most unfavorable environment for the reception and nourishment of the graft. To obviate the possibility of subsequent infection in cases which, from their past history, seem unfavorable, and in order to furnish healthy tissues in which to implant the bone graft later, it has been the author's practice to excise the scar at a preliminary operation, laying bare

the bone ends, and replacing the scar by plastic flaps of healthy skin, subcutaneous tissue, muscle, fat, etc. If, as has usually been the case, satisfactory healing of the wound takes place, the bone graft operation follows after a period of from ten days to two weeks. By means of such a two-step operative procedure, healthy tissue is provided for the subsequent implantation of bone, and a successful sequence is more reasonably certain.

Source of Graft Material.—Owing to its accessibility and favorable contour, the tibia, perhaps of all the bones of the body, as a source of graft material affords the greatest ease of technic. Moreover, bone from the tibia is nearly always preferable for grafting purposes, not only on account of the dimensions and the plane surface of this bone, which permit of a wide choice in the selection of material, but also because of its characteristic strength and osteogenic activity. In the treatment by bone graft of the foregoing series of 100 cases of fracture, the tibia with few exceptions furnished the graft material. The exceptions were in cases of sliding grafts to restore loss of substance in the humerus, femur or tibia, and in one instance of synthetic transplantation of tissues to form a new finger, in which case bone was transplanted from the clavicle.

Avoidance of Operative Trauma.—There are traumatic influences which have an important bearing on the success of a bone graft operation. It is necessary to avoid certain faults in technic, such as excessive length of operating time, with the resultant drying of the graft or host tissues from contact with the air, rough use of the retractors, poor mechanical fit of

graft, absence of coaptation of similar bone layers, or direct trauma from wedging or crushing by the chisel and mallet.

Table 2 permits a comparison of the average operating time with the shortest in certain cases, and has been inserted because it is believed that in no other class of surgery does length of operating time so materially influence results. In this work, in which we are deal-

TABLE 2.—SUMMARY OF TIME REQUIRED IN BONE GRAFT OPERATIONS, ACCORDING TO SITE OF INJURY

Bone	Time of Operation—	
	Average	Shortest
Humerus	1 hour	45 minutes
Radius	47 minutes	25 minutes
Ulna	33 minutes	19 minutes
Femur	55 minutes	21 minutes
Tibia	23 minutes	14 minutes

ing with rigid tissues, every effort must be made to maintain to the fullest possible extent the viability of the transplanted bone, a condition largely dependent on the early union of graft tissue with host tissue and on the adequate establishment of nourishment. Drying

Fig. 13 (Case 3).—To restore lost function of hand, the synthetic transplantation of soft tissues and bone was undertaken in a two-step operative procedure. Skin and soft parts were first turned up from the chest wall to form a boneless finger. Through a pedicle left attached to the chest wall, supply of blood was furnished until circulation with the hand was thoroughly established. The hand and arm were immobilized in plaster for four weeks. In the second operative step, the boneless finger was first cut loose from the chest wall. A tibial graft, inserted through the soft parts, was then mortised firmly into the os magnum. A sliver graft, indicated by the arrow, was affixed alongside for increased osteogenesis. The roentgenogram was taken four weeks after the implantation of the grafts, which now have become firmly united to the bones of the hand.

of the tissues from contact with the air should be constantly guarded against, not only by the use of saline

solution, but by completing the operation in the shortest possible time consistent with good work and with minimum trauma.

Final Results in Forty-Eight Cases.—Too short a time has elapsed to pass judgment, at the present date, on the entire series of 100 cases of fracture. However, in forty-eight cases that were treated before March 1, 1919, and have, therefore, afforded opportunity for observation over a period of at least ten months, we feel justified in reporting definite conclusions.

Of these forty-eight cases, the results in six are questionable; the grafts are still in situ and the roentgen ray reveals bone growth, but the wounds were primarily infected and there yet remain one or more sinuses. Three of these questionable cases, however, show favorable indications of ultimate good results; the other three cases will probably be failures.

Four of the forty-eight cases are definite failures. Of these, one case, a sliding inlay from a tibia to a femur to stabilize a resected knee, was complicated by pneumonia five weeks after the operation; sinuses broke out on both sides of the knee, with a resulting infection of the entire scar tissue of the knee and a failure of part of the graft to "take." Of two radius cases that were failures, one showed a positive Wassermann after, but not before, the operation; and the patient himself removed the fixation dressing on three different occasions. The other radius case showed a bad infection of dense scar tissue. The fourth, and last case of failure, was a humerus case with loss of three inches of substance, and with much scar tissue. The wound broke down, and examination by roentgen ray revealed that the lower end of the graft was not attached to the distal end of the humerus.

Subtracting this group of ten cases, of which four are definite failures and six questionable cases, we have thirty-eight cases remaining, all of which have shown perfect results in respect to postoperative primary healing of the wound, proliferation of new bone as demonstrated by the roentgen ray, and restoration of function. This yields a rate of 79 per cent. perfect results, with a possibility of an ultimate 85 per cent., should three of the questionable cases prove successful.

A complete report of all the plastic operations performed at U. S. Army General Hospital No. 3 will be published as soon as sufficient time has elapsed to permit of trustworthy deductions.

SUMMARY

The following conclusions are based not only on a study of cases and results at U. S. Army General Hospital No. 3, at Colonia, N. J., but also on the author's

previous experience with over 1,800 cases treated by bone graft in civilian practice, as well as in extensive animal experimentation. It is believed that the careful observance of these points is essential to success in this class of work.

1. Early Observation of Wound.—A careful study of the wound should be made before it has healed, if possible. The type of infecting organism (*Streptococcus hemolyticus*, gas bacillus, etc.), the nature of the clean-up operation and the manner of healing of the wound should be noted.

2. Time to Operate.—In a few cases it is permissible to operate after the wound has been completely healed for a period of two months, while in others, on account of possible latent infection, it may be advisable to delay the final plastic work for at least six months. In some of the unfavorable latter cases, a two-step operative method may be followed, consisting of a preliminary excision of scar tissue with replacement by a healthy skin flap, muscle, fat, etc., followed after a period of from ten days to two weeks by the final bone plastic operation.

3. Immediate Preoperative Observations.—For the purpose of determining the existence of latent infection, splints should be removed, and deep massage and rough manipulation should be practiced for a period of from one to two weeks prior to the operation. During

this time the temperature should be observed, and the parts should be carefully examined for local tenderness or any evidence of a recrudescence of infection. The field of operation should have a forty-eight hour preparation, iodine technic being preferred.

4. Plan of Operation and Choice of Incision.—By means of roentgenographic and physical examinations, the proposed plan of operation, especially in respect to location of graft, should be determined before incision is made. If possible, the skin incision should not lie directly over the proposed bed of the graft, and the operation should be so planned that the graft may be covered without undue tension of skin and,

if possible, so placed that it comes in contact with healthy tissue instead of scar tissue. In several cases in which this has been accomplished, the graft has healed in by primary union, whereas the scar, even at a

Fig. 14 (Case 3).—New finger six weeks after last operation. The patient is now able to grasp and hold objects with his thumb and grafted finger.

Fig. 15 (Case 4).—Case of compression fracture of third, fourth and fifth lumbar vertebrae caused by fall in dugout. Panel of vertebrae (from clay model of case), showing relief of condition by a tibial graft inlaid into spinous processes from first lumbar to first sacral vertebrae.

considerable distance from the graft, has broken down completely. In cases of extensive loss of bone, the scar tissue may be pushed to one side, in order that the graft may lie in healthy tissue. Drainage wicks of any kind should never be inserted at the time of operation.

5. *Duration of Operation.*—It is believed that the shortest possible operating time consistent with good work and with a minimum amount of trauma is requisite to successful results in these cases.

6. *Use of Motor-Driven Instruments.*—These are essential: (a) on account of the necessity for rapid work in order that drying and traumatization of the graft tissues and host tissues may be avoided; (b) in order that a cabinet-maker fit may provide for mechanical fixation of parts and for the operation of Roux's law of frictional stimulus to bone growth with a view to an early and adequate establishment of nourishment to the graft; and (c) on account of the necessity for the fulfilment of the law of anociassociation. The motor outfit with its various tools to produce automatic fits seems indispensable. The motor-saw, when used by the proper technic, does not heat nor glaze the bone.

7. *Adequate Length of Graft.*—The graft should always, when possible, be of the inlay type, and sufficiently long to extend into each fragment for a distance of at least 2 inches, and always beyond the sclerosed area. The gutter should extend well into the healthy marrow of the host-bone, with which the marrow of the graft should be amply contacted. It is exceedingly important that the bridge of marrow from the marrow canal of one fragment to that of the other should be restored for the transmission of blood vessels, bone cells, etc.

8. *Type of Graft.*—The graft should, if possible, be autogenous, consisting of all the bone layers, namely, periosteum, complete thickness of cortex, endosteum and marrow substance; and it should be so inlaid that the fit is perfect, with exact apposition of corresponding layers of graft tissue to those of the host fragments. Such a contacting fit not only favors the mechanical fixation of the fractured bone and the graft, but also the very potent frictional stimulus to bone growth, emphasized by Roux.

9. *Supplemental Grafts for the Purpose of Osteogenesis.*—Small silver grafts placed alongside the principal fixation graft are most efficacious in supplying additional foci for bone growth.

10. *The Graft as Main Fixative Agent.*—Fixation should always be secured by the graft itself, and not by metal plates or other foreign material, since it is the stimulation from the stress carried by the graft itself that is largely responsible for the healthy metabolism of the graft and for bone growth.

11. *Suture Material.*—The graft should be held in place by a minimum amount of absorbable suture, preferably kangaroo tendon, which is the ideal material for this purpose, in that it is tolerated by tissue, readily absorbable, very strong and reliable. Fine absorbable suture material should be used for the skin and underlying soft parts.

12. *Postoperative Fixation.*—The limb should be firmly immobilized by a plaster-of-Paris cast for a period of from eight to ten weeks following operation, and as long thereafter as the roentgen ray shows it to be necessary. Emphasis should again be placed on the importance of using absorbable skin suture material in order that the plaster dressing need not be disturbed until time for the removal of the splint.

DIAGNOSIS AND SURGICAL TREATMENT OF INTRATHORACIC GOITER

PALLIATIVE TRACHEOTOMY; TRACHEOSTENOSIS *

GUSTAV SCHWYZER, M.D.

MINNEAPOLIS

The term intrathoracic goiter indicates in a general way that the thyroid growth is located in the chest. Woelfler used to classify these goiters as substernal, subclavicular and endothoracic. Others speak of partial or total intrathoracic goiters. None of our goiters belong to the endothoracic or total intrathoracic group; they were all complicated by a goiter on the neck itself.

Fig. 1.—Intrathoracic goiter in Mrs. R., aged 57.

In order to eliminate confusion with the ordinary struma profunda projecting into the sternal notch, I shall consider only those goiters that reach to the height of the second rib or lower.

ANATOMY

In order to gain a clear understanding of the symptoms of intrathoracic goiter we must consider for a moment its anatomic relations.

The aperture in the thorax anteroposteriorly measured from the upper border of the sternum to the first dorsal vertebra is only 5 or 6 cm. in distance, and the lateral diameter taken through the middle of both ribs is from 9 to 10 cm. It is evident, therefore, that the aperture into the thorax is the most dangerous place if a goiter is located here, as this bony ring cannot give, and compression of the adjacent organs going through is unavoidable. If the goiter goes through

* Read before the Minnesota Academy of Medicine, Oct. 8, 1919.

the aperture into the *cavum mediastini*, conditions become more tolerable. If it stays back of the sternum, it compresses particularly the trachea. The esophagus does not give any symptoms in most cases; though

Fig. 2.—Intrathoracic goiter in Mrs. C., aged 63.

difficulty in deglutition speaks for a retrosternal goiter.

The *cavum mediastini* is bordered in front by the manubrium sterni, the anterior ends of the clavici and the first ribs, posteriorly by the first three dorsal vertebrae, on the side by the parietal pleurae, and inferiorly by the big blood vessels, the vena and arteria anonyma, the arch of the aorta, and the pericardium. The organs we deal with in this *cavum* are the vena anonyma, back of it the truncus anonymus arteriosus, the common carotid, and the subclavian artery, the nervi vagi, recurrentes and phrenici, the thoracic duct, the tip of the lungs, the trachea and the esophagus.

DIAGNOSIS

A considerable aid in the diagnosis is a good history. We may learn that the patient had a goiter for years, and that this goiter disappeared or "was cured," as the patient often expresses himself. He may mention that breathing was always labored at the least muscular effort, and difficulty in breathing remained even after the disappearance of the goiter on the neck. In addition the patient may say that in bed he is forced to lie in a certain position. Often he requires no pillow or, on the other hand, he may have to elevate his head unusually high. Should he change the well-chosen position of the head unconsciously in his sleep, the patient awakens feeling choked, has to sit up straight in bed, or runs to the window in an effort to inhale air. Sometimes he spends night after night in a chair, fearing the recurrence of one of these spells.

INSPECTION

At times such a patient has almost a comical appearance, carrying his head in a high and stiff manner. Again, we may find the head bent forward with the chin approaching the sternum.

Physical Examination.—If no goiter attracts our attention, we now start with a thorough physical examination of the chest. Percussion may give us a distinct dullness over the sternum, or over the sternum and one side, or over both sides. This symptom is a more constant one than the findings perceived through auscultation. The latter examination, though, may help us at times in our diagnosis. The breathing in the upper chest may be so light and superficial that it attracts our attention. This finding points to the fact that there is an impediment to the breathing. The lung may be squeezed to the side, so much so that it cannot inflate. Or a bronchus may be compressed.

Whether or not there is a goiter plainly visible, with or without dyspnea, we are bound to make a careful palpation of the neck down into the jugulum as far as we can reach. We may find a palpatory resistance in the jugulum which is constant or which appears only during deglutition. The larynx may stand very low. We then speak of a ptosis of the larynx. Its excursion during deglutition might be markedly reduced. Consequently we must always remember deglutition when we palpate.

If hoarseness exists, then the laryngoscope will tell us of a paresis or a paralysis of the vocal cord. Again we are a step ahead in the diagnosis. True, there

Fig. 3.—Intrathoracic goiter in Mrs. R., aged 53.

are some cases with extreme dyspnea in which the more skilful laryngoscopist will be unable to succeed in seeing far down into the trachea. I will add that not only the vocal cords but also the lower part of the trachea must be included in the laryngoscopic picture.

Pathologic Structure.—At times there are symptoms existing which originate from the special pathologic structure of the goiter, and these also have to be considered.

Fig. 4.—Intrathoracic goiter in Mrs. O., aged 64.

The malignant intrathoracic goiter in its initial state is of course intracapsular and cannot be diagnosed. Should we have severe dyspnea and especially paralysis of the recurrent laryngeal nerve together with some metastatic tumor, the diagnosis becomes certain, but a cure impossible.

Fortunately, most of the intrathoracic goiters are of benign nature. In this group belongs the toxic or exophthalmic intrathoracic goiters with their characteristic symptoms: tachycardia, tremor, disturbances of the nervous system, and the various eye symptoms including exophthalmos.

Heart Symptoms.—The connection between the goiter and the heart has long been recognized. We commonly speak of a "goiter heart." A toxic goiter or the pronounced exophthalmic goiter is responsible for the thyrotoxic heart. But there is another important heart affection more commonly found in intrathoracic goiter called the "mechanical goiter heart." It is an accepted thought that pressure of the tumor on the large blood vessels as well as on the nerves, especially the cardiac branches of the sympathetic nerve, can bring on this condition of the heart. On examining the heart itself we commonly find its valves free from murmur. It usually appears enlarged, but because of the dullness mostly constant in the chest, the outlines of the heart become indistinct. The heart action is confused, irregular and accelerated.

A very characteristic symptom is the net of dilated veins on the neck and upper chest anteriorly. The superior vena cava, which brings all the blood from

the upper part of the body into the right atrium, suffers principally through this pressure. That blood is now drained through some side channels (the *venae costalis superiores*, *hemiazygos* and *azygos*) into the inferior vena cava. This phenomenon was observed in one of my cases (Miss H.). Her history tells us that at one time she was treated at a hospital for these varicose veins.

The arterial blood vessels also can suffer.

There are cases reported in which one common carotid and the radial artery of the same side were only faintly pulsating, owing to the severe pressure from an intrathoracic goiter.

Roentgen-Ray Examination.—Good roentgenograms and a fluoroscopic examination are, indeed, a welcome aid for the diagnosis. There are some rare intrathoracic goiters, for instance, tumors in the chest from aberrant thyroids, in which the roentgenographic examination is the only means by which we can detect such a disease. We should have an anterior and a lateral roentgen-ray view, lateral especially, as the intrathoracic goiter is located particularly in the anterior upper portion of the mediastinum. If during deglutition in the fluoroscopic examination the tumor follows the movement of the larynx and trachea, regularly and synchronously, the last doubt in the diagnosis is removed.

Indications for Operation.—Whether or not a case of intrathoracic goiter is operable does not depend on the degree of dyspnea, nor does it depend on the pressure of the nerves, or on any of the symptoms men-

Fig. 5.—Intrathoracic exophthalmic goiter in Mr. C., aged 49.

tioned; but it does depend on the heart. A degenerated heart muscle, a pronounced myocarditis bringing on secondary changes of the other inner organs, is a contraindication for operation. But even after carefully weighing the various heart symptoms, we are

always taking a certain risk, for we have no direct test which will reassure us that the heart is sufficiently resistant for the operation.

SURGERY

A retrosternal goiter with its precarious dyspnea should be operated on without much delay. We must remember that choking spells do not repeat themselves indefinitely, for with each such dyspneic attack the patient is one step nearer his grave. I shall never forget one case at Kocher's clinic which resulted fatally. It was a case in which dyspnea increased so rapidly that not even a tracheotomy could be done. The patient, who had an intrathoracic substernal goiter (found at necropsy), was ordered to bed. He disobeyed the physician's orders, left his bed during the night, and by doing so brought on a new spell of dyspnea, this time fatal.

It is desirable that the operation be begun under local anesthesia if the dyspnea is very marked or if the goiter is of toxic nature. Concerning this point, one of my cases will open an argument. A woman, aged 64, with a subclavicular goiter, died from pneumonia on the fourth day following the operation, which was done under local anesthesia. I am inclined to think that the severe mechanical injury resulting from working directly on the trachea was sufficient cause for the death. It has been my experience that even ordinary goiter operations may be complicated by an acute, putrid bronchitis. For this reason de Quervain in Bern avoids as often as possible dissecting the isthmus free from the trachea unless there is a strict indication for the removal of the isthmus.

Excitement must be kept away from the patient as much as possible. Very important too is the position of the patient on the operating table. Let the patient be the judge to tell us whether the head lies correctly. Only in apathetic patients must we be guided by the stridor. If the latter is minimized, the most desirable position is found. It is of the utmost importance to have an eye on the respiration. If the extreme dyspnea increases to a degree too dangerous for life as the operation progresses, a tracheotomy must be made and a cannula of sufficient length must be introduced to reach beyond the point of obstruction. I prefer the flexible cannula devised by Koenig.

This operation, which is only palliative, proves to be very difficult at times, especially if the trachea is covered by the thyroid mass above the manubrium sterni. The most desirable way that the operation can be performed is to divide the isthmus wherever it is most feasible and dissect it bluntly as much as possible from the trachea.

While surgeons formerly practiced a two-stage operation, we today excise the tumor regardless of a tracheotomy. The tumor itself must be bluntly enucleated from within its capsule. Its blood vessels as they present themselves require exact attention. Only in this way can fatal hemorrhage be avoided. I always start my goiter excisions by tying off the upper horns. I was astonished to find that no severe hemorrhage ever followed. In one case I compressed temporarily with gauze, but I never inserted liquid wax, a procedure recommended by competent surgeons. Should a large blood vessel like the anonyma become torn, the question in my mind remains open whether the hemorrhage can be controlled without resecting the sternum and the clavicles, a procedure which in itself carries unavoidable complications.

Kocher has devised a good clamp of great value for

traction on such intrathoracic tumors. The instrument compresses the tumor, thus avoiding profuse bleeding. The sharp hooks of the instrument prevent it from slipping, and the tumor, therefore, must follow the traction.

I have drained every cavity which naturally exists after such goiter excisions with fine, flexible, rubber tubes. The drains are removed as soon as the secretion ceases. It is astonishing in how short a time the obliteration of such cavities takes place.

Let us consider my own cases. All these intrathoracic goiters were of benign nature; one was a double cyst, two distinctly toxic, one exophthalmic, and the others were colloid, parenchymatous or cysto-parenchymatous goiters. Two were in men and fourteen in women, although the statistics generally favor the male sex for intrathoracic goiters.

The one exophthalmic case, in a man, aged 49, I shall report somewhat in detail:

I performed the ligation operation on both upper horns in January, 1912. The patient, who had the characteristic tremor, perspiration, sleeplessness, sick feeling in the stomach and abdomen, and loss of body weight (160 pounds), showed a pulse of 122 when quiet in bed. The characteristic symptoms existed over the gland, but there was no exophthalmos. The operation had the desired effect. From notes taken in January, 1914, I learned that he improved generally within the two years after the ligation. His pulse came down to between 106 and 110. Still he suffered from his heart beating and from slightly dyspneic breathing. At this examination the laryngoscope detected a deviation of the trachea to the right and compression of the tracheal rings.

Having felt the intrathoracic part of the goiter at the first operation, I proceeded with the excision of the goiter in January, 1914. It proved to be a bloody and difficult operation. The tumor tore in different places, but luck was with me. The patient left the hospital two weeks later

Fig. 6.—Intrathoracic goiter in Mr. M., aged 56.

with a pulse of 76, and in June, 1914 (same year), he writes that he does all the work without a hired man on his farm of 160 acres. His weight is now 200 pounds, his pulse 74, and he eats and sleeps well.

One of my toxic cases was unusual on account of acute mental disturbance lasting about thirty hours following the operation. In her confusion the patient tore the bedclothes and constantly tried to leave her bed.

Two cases showed a plain "mechanical heart":

Mrs. R., aged 57, had a very irregular pulse at a high rate without any pathologic findings over the valves. To my surprise there were only 100 pulsations on the second day following the operation.

Mrs. C., aged 63, had a perfectly normal heart. The tone over all the valves was clear, but the function of the heart was increased in frequency and energy. The pulse rate, previously up to 132, became normal forty-eight hours after operation. The heart in any of our thyrotoxic patients has never responded so promptly, that is, never has come down to a norm in such a short time following excision.

In three cases of the series my diagnosis was incomplete. I thought I had to do with *strumae profundae*, which proved to be intrathoracic goiters.

Since I always found a goiter on the neck, my attention was drawn immediately to the diagnosis, as I never failed to find dyspnea present, the main symptom.

Owing to the fact that most of my cases date back a number of years when roentgenology had not reached the point of perfection of today, I depended in the first place on the clinical symptoms.

TRACHEOSTENOSIS

As dyspnea caused by compression of the trachea is the main symptom in intrathoracic cases, I may be permitted to consider this phenomenon for a moment. A normal trachea has the form of a stirrup. Compression by a goiter at any height naturally changes this picture. We have accurate knowledge from specimens taken at necropsies and we know that the natural picture of the trachea can be distorted in almost every way. There may be a sheath formation, or a half-moon formation. The trachea may be strictured circularly by a circular goiter. The trachea may also be deviated to one side; it may be distorted by two different goiters on different sides and even at different heights. There may be a trachea twisted in such a way that surgeons formerly spoke of a scoliosis.

At the beginning of the nineteenth century, a French surgeon (Lullier-Winslow) described the sheath formation of a trachea. Demme, a surgeon in Bern (Switzerland) in the first half of the nineteenth century, demonstrated the same tracheal deformity with brilliant illustrations that have impressed surgeons.

An interesting controversy was started by Rose in the eighties. He had a series of sudden deaths. Some occurred at the time of the goiter operations, and others hours following the operations. He thought that more important than the compression of the trachea itself was the fact that the trachea became softened at the place of pressure. He explained this softening through fatty degeneration. His statement encouraged a number of eminent surgeons of those days to look up matters histologically. The lengthy debate ended in the accepted fact that no fatty degeneration existed in the cartilage, but that an atrophy of the cartilage became evident. Rotter then found the interesting point that the membranous bands between the cartilaginous rings were elongated in all these cases of compression of the trachea. It was then left to Woelfler to settle this

argument, and at the same time bring out facts which led us to believe that the deaths which Rose had on the operating table and which he believed to be due to the softening of the trachea resulted from a collapse of the trachea at inspiration. At the time of expiration, such trachea freed through operation will fill with air like the sail of a boat; but during inspiration the trachea aspirates itself, that is, collapses. The goiter on the trachea is a support and acts like a splint.

I had the opportunity to witness this phenomenon in three cases, though nonintrathoracic. Not having been compelled to make a tracheotomy for any of my intrathoracic goiters, I may be permitted to mention briefly those three cases. They were all in girls from 15 to 20 years old, and all were double goiters. In two of them I was forced to add a tracheotomy within twelve hours after the operation. The dyspnea following the excision gradually became more marked; intercostal inspiration was exceedingly plain. The third patient, with a double struma vasculosa, was breathing with marked stridor. Excision of one goiter cleared the respiration, but as soon as the other side was removed the trachea collapsed at inspiration. I acted quickly and incised the trachea at once. All three patients recovered.

Tracheostenosis very seldom requires surgical correction at the time of operation. The trachea cannula, however, must always have its place among the instruments.

CONCLUSION

If I may be allowed to compare my work in intrathoracic goiters with the general work in goiters, I am impressed by the rather gratifying results, in view of the fact that no other operation has more marked and immediate success. The patient who, with his labored breathing and his cardiac trouble, appears to himself and to others an invalid is now, through removal of the growth in the chest, restored to health immediately.

Maternity Benefit Systems.—The United States is the only one of the leading industrial countries of the world to have no system of state national assistance to maternity according to the Children's Bureau of the U. S. Department of Labor. The countries having such systems are: Australia, Austria, Bosnia, Denmark, France, Germany, Great Britain, Herzegovina, Hungary, Italy, Luxemburg, Netherlands, New Zealand, Norway, Roumania, Russia, Serbia, Sweden and Switzerland. Few of these countries offer benefits to all mothers, but there is a general agreement that wage earners shall be included. The benefits provided consist usually in money, either a lump sum or weekly payments, and occasionally in medicine and medical and surgical services. The expense of the benefits is most frequently shared by the wage earner, the employer, and the state, the wage earner contributing the largest share. In Australia and France, however, the government bears the entire cost. Australia in 1913-1914 paid out \$3,284,839 in maternity allowances, and France calls on the national government for over \$1,000,000 annually and gets another \$1,000,000 annually from local government for this purpose. The English benefits are part of a health insurance scheme for wage earners, of which the government bears a share equal, in the case of the women, to one fourth of the total benefits. In New Zealand there is a voluntary system of health insurance, which includes a maternity benefit, but it reaches so few mothers as to make its effect almost negligible. The method of attack is not through maternity benefits but through adequate nursing service, hospital and medical care, and instruction in the hygiene of maternity and infancy. At present the death rate of New Zealand is the lowest in the world. Australia, on the other hand, gives a maternity benefit of 5 pounds, over which there is no supervision.

Clinical Notes, Suggestions, and New Instruments

IMPROVEMENTS IN TECHNIC FOR THE OBSTETRIC NURSERY

HERBERT THOMS, M.D., NEW HAVEN, CONN.

The daily use of the devices herein described has given excellent results in the maternity department of the Grace Hospital, New Haven, Conn. The first is a simple and efficient method for the identification of babies in the obstetric nursery and the second is a new instrument for use in stretching and retracting the foreskin of newborn babies.

Fig. 1.—Aluminum tag for identification of infants.

In reading the transactions of the Brooklyn Medical Society for May 2, 1919, I became greatly interested in the various methods that were there described for the identification of babies. All of the methods were efficient, but their adaptability to all maternity hospitals was not great. After some experimentation, the method here depicted was adopted with uniform success, not only because of its simplicity but particularly because of its adaptability.

A small aluminum tag the size and thickness of a 5-cent piece (Fig. 1), with a raised edge and a perforation near the edge, is used. This is readily written or engraved on with a steel pencil or machinist's stylet. This makes, of course, an absolutely inefaceable record. Immediately after the birth and tying and cutting of the cord, this tag is tied around the baby's neck by means of linen tape, three knots being used in tying. This tape is not only very strong but also unabrasive. Aluminum is employed because it is noncorrosive, very light, inexpensive, nonabrasive, and readily written on with the steel pencil.

The reaction of the mothers in the hospital since the adoption of this method is interesting. Not only have they been delighted with their "tagged babies," but they insist on taking their babies home with the tag adornment undisturbed.

Fig. 2.—Modification of hemostatic forceps for stretching and dilating foreskin.

The instrument shown in Figure 2 is modified from hemostatic forceps. Every one who has used the ordinary hemostat in stretching the foreskin of babies realizes how readily the instrument slips away from the penis. In order to obviate this and to make a more even dilating surface, the instrument here shown was devised. About 0.5 cm. from the end of the forceps on each side is a marked concavity, the purpose of which is readily understood. After the adhesions between the foreskin and the glans have been broken up with an ordinary probe, this instrument is introduced between the glans and the foreskin, and dilatation is easily accomplished.

59 College Street.

A CHAIR FOR SPINAL PUNCTURE*

NORMAN E. WILLIAMSON, M.D., STOCKTON, CALIF.
Pathologist, Stockton State Hospital

In the ordinary method of performing spinal puncture it is difficult to get the patient in the right position. Even when the patient is held by attendants, as has been my practice, there is the possibility of sudden movement closing, more or less, the space between the vertebrae. If a flexible gold or platinum iridium needle is used, there is no danger of breaking; but one may experience considerable trouble in inserting the needle, especially after it has been repeatedly kinked. With the back properly bowed and the needle inserted, it is at times found that the needle is directed too near the perpendicular, and the fluid runs down the needle and is lost on the back. This necessitates a troublesome change of position.

Chair for spinal puncture; arrow points to needle.

I have devised a spinal chair which holds the patient in the correct position so that no attendants are necessary. The front of the seat is so raised that the line of its fall to the lowest point forms an angle of 27 degrees to the horizon. Back of this is a 5-inch curved rise to prevent the patient from sliding off backward. When the patient is sitting at this angle with the back curved outward and the needle inserted, the point of the needle is elevated so that the fluid always drips into the test tube.

A webbing strap with buckle attached to the back of the chair is fastened in front of the abdomen, and the curve of the back is obtained, and fixed by an adjustable bar brought down over the scapulae. The rod passing through this bar can be fixed by a thumb screw to any point in slots in uprights erected at each side opposite the lowest point in the seat.

The curvature of the back is maintained by three points of fixation, and the puncture is made with ease and safety.

* From the Stockton State Hospital.

ACUTE MYELOID LEUKEMIA SIMULATING
MENINGITIS

E. E. H. MUNRO, M.D., St. Louis

REPORT OF CASE

History.—Miss M. W. (589), aged 17, telephone operator, was admitted to the City Isolation Hospital, St. Louis, Sept. 17, 1919, having been transferred from the St. Louis City Hospital because it was suspected that she had meningitis. Her past general health had been good. Of significance in the past history is the fact that she had had an alveolar abscess of the superior right maxilla five months before admission. The abscess had been lanced three times during the past three months. It had given no trouble for the past two and a half months. Occasionally during the past four months the patient complained of swelling of the feet in the evening. Three times she fainted while at work.

The present illness began five days before admission with headache (occipital) and slight vertigo. The patient vomited twice during the first day of illness, although she was not sick enough to go to bed. The next day the patient remained up but complained of vertigo and headache. She vomited four times and slept poorly that night. On the fourth day, fever and delirium developed. On the fifth day, the patient was in a stupor. The family physician sent her to the city hospital, where stiff neck and positive Kernig's and Babinski's signs were noted. A spinal puncture was performed that evening and repeated the next morning. The fluid was blood stained and under increased pressure. Smears and cultures from the fluid were negative. The patient was transferred to the isolation hospital as suffering from meningitis.

Examination.—On admission to the isolation hospital the patient was semiconscious, the temperature was 105, the pulse 120, and the respirations 38. There was stiff neck, mild opisthotonos, and slight external strabismus; the right pupil was more widely dilated than the left, and both pupils reacted to light. At intervals there was a twitching of the right side of the face. Pressure over the right ear caused moaning and marked twitching of that side of the face. Both ear drums were normal in appearance. The teeth were in good condition. The scar of the old alveolar abscess was seen, but there was no evidence of active infection. The tonsils were moderately enlarged and red. The superficial lymphatics, cervical, axillary, epitrochlear and inguinal, were all slightly enlarged. The systolic blood pressure was 135, and the diastolic, 75 mm. The upper margin of the liver dulness in the right nipple line was at the fifth intercostal space; the lower border was palpable 6 cm. below the costal margin in the same line. The spleen was palpable 6 cm. below the level of the umbilicus in the left nipple line. It also extended 4 cm. to the right of the midline of the abdomen. A notch was made out at the level of the umbilicus. There was general rigidity of the extremities, more marked in the upper extremities. Kernig's sign was positive. The knee jerk was sluggishly active on the left, and absent on the right. On admission the plantar reflexes were hyperactive; on the following day, Babinski's reflex was positive; on the third and fourth days, all plantar reflexes were absent. The blood count revealed: 3,080,000 red blood cells; 720,000 white blood cells; hemoglobin, 40 per cent. In the stained blood smear there were a number of large mononuclear cells, the size of a myelocyte, with a nucleus which almost completely filled the cell. This was also found in a lymphocyte which could not be accurately classified. The differential count on admission was: myelocytes, 66 per cent.; myeloblasts, 6 per cent.; polymorphonuclear neutrophils, 16 per cent.; large mononuclears, 10 per cent.; eosinophils, 2 per cent., and normoblasts, 6.

Diagnosis.—A diagnosis was made of leukemia with hemorrhage into the central nervous system.

Treatment and Results.—Spinal puncture on four occasions revealed a yellowish pink fluid under increased pressure. Smears and cultures disclosed no organisms. The Wassermann, and tuberculosis complement fixation tests were negative. Blood cultures were negative. A catheterized specimen of urine showed albumin and a large number of hyaline and finely granular casts.

For four days the rectal temperature ranged from 103 to 105.6. On the last two days there was involuntary urination and defecation. Several times a cool tap water enema was returned blood stained.

Necropsy Findings.—The patient died on the fifth day after admission. Necropsy was performed four hours after death by Dr. Sherry, city pathologist. No evidence of an inflammatory condition anywhere in the central nervous system was found. There was a very marked engorgement of the vessels of the meninges and an acute edema of the brain and cord. No gross point of hemorrhage was found. The omentum, mesentery, and intestinal serosa showed many minute hemorrhages. The intestinal mucosa showed diffusely scattered minute hemorrhages. There was a small amount of free blood in the lumen.

The chambers of the heart were filled with the characteristic greenish yellow clots. Microscopically the heart showed great engorgement of the vessels and marked mononuclear infiltration between the muscle columns. This engorgement of the vessels and mononuclear infiltration were seen in the liver, spleen, ovary, pancreas, heart, kidney, cerebellum, spinal cord, coverings, lung, lymph glands and intestine. The capsule of the liver was thickened, and directly beneath it and almost completely separating it from the parenchyma was a layer of mononuclear cells of varying thickness.

The liver and spleen were very large. The spleen weighed over 13,000 gm. The spleen showed a number of sharply outlined yellowish, lymphoid tumors giving the appearance of anemic infarcts.

There was general hyperplasia of lymphoid tissue with notable enlargement of the mesenteric lymph glands and of Peyer's patches.

COMMENT

Although the history of onset and the clinical picture presented by this case would lead us to suspect strongly a meningitis, it is evident that the whole picture was produced by the leukemia.

MILK AS A VEHICLE FOR CASTOR OIL

LOUIE C. BOYD, Williamsport, Pa., writes: "I was much interested in extracts from an article originally published in THE JOURNAL on giving castor oil. I want to object emphatically to the giving of medicine in food and especially in milk. Milk is too valuable a food for long usage (in tuberculosis, for instance) to have the taste for it changed to utter disgust, with inability to take it with any relish because some medicine was given temporarily in milk. In the matter of castor oil, I suggest the following ways: 1. Hold the nose and swallow the dose. 2. Hold a piece of ice in the mouth for a time and then proceed as under 1. 3. Put diluted lemon juice in a glass; rub the rind on the edge of the glass; pour in oil and a small amount of diluted juice on top. If desired, a pinch of sodium bicarbonate can be dropped in, which will make it froth. 4. Put oil in the froth of soda pop."

COMMENT.—The objection to the use of castor oil in milk or in any other food is well taken; and such objection was voiced in the article on castor oil referred to. The fact remains, however, that there are some patients who prefer to take it in milk, and that the odor of pure unspoiled castor oil is so faint as to be unobjectionable. All the methods suggested by the writer are useful. Especially interesting and, no doubt effective, is the use of lemon juice, as detailed under 3; though, unless the diluted lemon juice is sweetened, children would refuse to take the dose.

SOME FACTORS IN BONE REPAIR

In the process of the bone repair which follows fracture and other injury of the osseous system, there is frequently considerable debris to be eliminated, such as blood clots, injured bone fragments and other damaged tissue. In addition to this necessity in the early stages of the reparative process, at a subsequent stage the preliminary or primitive new structure must in part be removed to give place to true bone. The excess of the provisional callus which is organized in connection with a bone injury as a rule gradually disappears, so that, as in the course of bone growth, bone resorption is likewise an active process in the later stages of bone repair. Osteoblasts are concerned first of all in the formation of primary bone from calcified cartilage. Until quite recently, it has been assumed that the so-called osteoclasts, which function in the formation of the large central marrow cavities of bones and in the metamorphosis resulting in the permanent bone, are concerned with the absorption and clearing away of cartilage in bone growth. They have been looked on as the scavengers of the developing osseous structures.

The investigations of Shipley and Macklin¹ at the Johns Hopkins University have thrown doubt on the assumed phagocytic action of the long recognized osteoblasts. By methods of vital staining with dyes belonging to the benzidin series of colors, it has become possible to identify throughout the body the special phagocytic cells which store the dyestuffs in the form of very minute dye granules, just as the mobile phagocytes of the blood engulf bacteria and other particles. Of late the term macrophage, first employed by Metchnikoff, has been applied to the entire group of phagocytic cells which are characterized by a uniform functional response to these colloidal dyestuffs. As a writer has recently remarked, the term macrophage is a physiologic designation, including within its compass very diverse morphologic elements. This similarity in staining reaction is but an expression of the phagocytic potentiality which these cells hold in com-

mon, and which manifests itself during their everyday existence in the ingestion and storage of certain elements of the surrounding tissue fluids. Some time ago it was pointed out in THE JOURNAL that the resorption of disintegrating calcified tissue in the secondary stages of osseous development, if judged by the results with vital staining achieved by Shipley and Macklin,¹ must be attributed not to the osteoclasts but to fixed macrophages represented by the ordinary reticulo-endothelial cells of the marrow reticulum.

It has now been demonstrated by Macklin² of the University of Pittsburgh that the same agencies function in the healing of bone wounds. Macrophages, which stain brilliantly with trypan blue, soon congregate at the site of the injury, where they increase in numbers and in size, and demonstrate increased phagocytic power. They assist in dealing with the tissue waste resulting from the trauma. These phagocytes are developed principally from the lymphocyte-like cells of the blood stream, but some are derived from local mononuclear cells with phagocytic potentialities. Most of them ultimately disintegrate in situ. Furthermore, according to Macklin, during the structural changes attending the transformation of provisional into permanent callus, trypanophil macrophages develop in the callus spaces from the reticulum cells and become numerous, large and phagocytic. They function in the removal of redundant bony spicules, their particular rôle being the absorption of the waste products formed by the breaking down of the matrix. When cartilage is present in the callus they also play a part in its removal. Their action here is thus the same as that of the macrophages of developing bone.

REGIONAL HEALTH SURVEYS

Napier Burnett,³ a British expert on public health, has recently given an interesting account of a regional survey of the hospital situation in a northern district in England. The success of the concentration and coordination of effort in protecting the health of troops which was exercised during the war seems to have opened the eyes of the British government to the possibilities of similar coordinated action during times of peace. Among the results is the formation of a ministry of health in Great Britain. Burnett's article indicates that the preliminary information on which action must be based is being gathered under this ministry.

The survey which Burnett describes covered an area of 4,000 square miles containing a population of two and a half million people. Data were collected covering the ratable value of property; the number and distribution of physicians and midwives in each locality; the various types of hospitals, dispensaries and convalescent homes; the birth rate and the infant

3. Burnett, Napier: *Edinburgh M. J.* 23: 387 (Dec.) 1919.

mortality rate; the population living in one, two and three room houses, and the transport facilities by rail and road. As would be expected, certain facts were brought out which, in spite of difference in medical organization in the two countries, are not without interest to American physicians. There were clear indications that the number of beds available in general hospitals was entirely inadequate, there being only 0.76 bed per thousand of the population. This was offset to some extent by the fact that there were as many beds available for infectious diseases as there were general hospital beds, and that, as contrasted with American conditions, there were a larger number of convalescent homes than exist in this country. The report also brought out that there was a lack of accommodations for medical as contrasted with surgical cases, that the distribution of the hospitals throughout the district was very unsatisfactory, and that the hospitals were having difficulties on account of lack of funds, just as they are in this country.

The report is of particular interest because certain aspects of the hospital question are at present under scrutiny here. One of the main points emphasized is the unsatisfactoriness of allowing the health machinery of a country to develop in a haphazard fashion. There can be no question that if the hospital development of a given region should be preceded by a survey in which data are collected concerning the distribution of the population and other important factors, such as those mentioned, the locations of hospitals would frequently be quite different from what they are. Now that an extensive hospital inspection is actually imminent in the United States, would it not be possible to combine with it the collection of information bearing on the health conditions of the population served by each hospital? It would seem that the situation presents a great opportunity for public service.

COMPENSATORY RESPONSES TO THE OXYGEN WANT AT HIGH ALTITUDES

Life at high altitudes is liable to be attended with symptoms of illness, whether the sojourn in the regions of lowered barometric pressure be on a mountain, in a balloon, or in an aeroplane. The essential cause of altitude sickness has been demonstrated repeatedly to be a lack of oxygen. Whatever the method by which the oxygen supply of the body is reduced, there will occur adaptive reactions having the evident function of furnishing in some way the indispensable element that is needed by the active tissues. All of the latter become sensitive to the oxygen want, but the responses are undoubtedly initiated in the central nervous system. They are definitely stimulated at first. In the effort to compensate for the reduction of the oxygen supply the blood, the respiration and the circulation may become involved. Thus, as has been indicated repeatedly by *THE JOURNAL*, there may be an increase in the amount

of hemoglobin in the body, and associated with this a redistribution of the red corpuscles whereby a reserve supply is thrown into the general circulation; deeper breathing may bring about increased ventilation of the lungs; an increase in the rate of blood flow may occur. Each of these responses tends to insure a more adequate supply of oxygen to the tissues.¹

In the acclimatization to oxygen want which follows the ascent of a mountain, the respiratory response is almost invariably the first to appear, beginning during the trip or almost immediately after the summit is reached. The increment in the number of erythrocytes comes more slowly and gradually. The alterations in the pulse rate may also be somewhat gradual. These effects, brought about by protracted residence at high altitudes, in turn disappear only gradually when the person returns to a lower barometric level.

As was recently pointed out² in relation to the more sudden shifts in altitude corresponding to the rapid flight of the modern aeroplane, similar adaptive responses are undergone by the aviator; but in contrast with the experiences of the alpinist, they develop much more quickly. Gregg, Lutz and Schneider,³ who have been engaged in extensive researches on these questions in the Medical Research Laboratory of the Air Service at Mineola, N. Y., have found that following the more sudden changes in atmospheric pressure and oxygen tension such as may occur in aviation, there is no such uniformity in the relative response of the different adaptive mechanisms as is found after the slower ascents on mountains. In other words, the relative values of the different compensatory reactions to low oxygen tension may differ as does the sensitiveness of different persons. The aeronautic physiologists report that the majority of men appear to make a well-balanced use of the three mechanisms for supplying oxygen. The ventilation of the lungs, the rate of blood flow, and the percentage of red corpuscles and hemoglobin are definitely increased. Some meet the new condition largely by increased respiration, and others depend almost entirely on an increased blood flow. In many individuals, during the early period of exposure to a decreasing oxygen, the burden of compensation is borne wholly by the circulatory and respiratory mechanisms; but later the blood changes relieve one or both of these mechanisms from a part of the burden. There is evidently an interdependence and interplay of the adaptive mechanisms. The same person may compensate differently in each of a series of emergencies associated with lowered oxygen.

In another respect also the compensatory reactions to a rapid reduction in oxygen differ from experiences in mountaineering. They disappear quickly when the

1. An excellent review of the evidence for these adaptive changes at high altitudes will be found in the *Manual of the Medical Research Laboratory*, War Department, Air Service, Division of Military Aeronautics, Washington, D. C., 1918.

2. Low Barometric Pressure and Changes in Circulation, editorial, *J. A. M. A.* **74**: 250 (Jan. 24) 1920.

3. Gregg, H. W.; Lutz, B. R., and Schneider, E. C.: Compensatory Reactions to Low Oxygen, *Am. J. Physiol.* **50**: 302 (Dec.) 1919.

oxygen tension is restored. There is little lag in the changes induced. Schneider and his co-workers³ conclude that the differences in the responses observed under these two different conditions of exposure to low oxygen depend, no doubt, on the suddenness with which the low barometric pressure and low oxygen percentage have been decreased, and on the extent to which they were lowered. In very slow and moderate changes, it is possible that no response may be evoked. They add that possibly the respiratory center, by virtue of greater sensitiveness, may react so much to the stimulus that the increase in respiration for a time cares adequately for the oxygen requirement of the body. In the more rapid decrease in oxygen tension, the respiratory and cardiac centers and very likely the vasomotor centers are stimulated at higher oxygen tensions and at about the same time. Consequently, under some conditions these two mechanisms serve almost equally to care for the oxygen need of the body. Evidently the problems of life at high altitudes must be considered somewhat separately for the various modes of ascent and sojourn in the upper reaches of the air. The slow progress of the Duke of the Abruzzi to a height of 24,580 feet in the Himalayas, and the more rapid rise of Glaisher to an altitude of 30,000 feet in a balloon, have already been far surpassed by the swift record altitude ascents of the modern aeroplane, to which neither sea nor land any longer bars the way.

THREE EARLY EPIDEMICS OF INFLUENZA

The history of epidemic influenza is a record of devastation and distress. The earliest record of influenza in America was made by William Hubbard:

In the year 1647 an epidemical sickness passed through the whole country of New England both among Indians, English, French and Dutch. It began with a cold and in many was accompanied with a light fever. Such as bled, or used cooling drinks, generally died; such as made use of cordials, and more strengthening, comfortable things, for the most part recovered.

This is cited by Guy Hinsdale, whose contribution to the Osler memorial volume is a record of the epidemics of influenza in 1647, 1789 and 1807, as recorded by Noah Webster, Benjamin Rush and Daniel Drake. Noah Webster, in addition to publishing his famous dictionary, was also the author of a "Brief History of Epidemic and Pestilential Diseases." In this book, published in 1799, Webster described forty-four instances of influenza, dating in Europe from 1174 and in America from 1647. All of these epidemics are associated with earthquakes, volcanic eruptions, comets, droughts and similar disturbances of nature. Thus Webster notes under the year 1647, "First catarrh mentioned in American annals. The same year with violent earthquakes in South America, a comet."

The epidemic of 1789 was described by Benjamin Rush, who, as Dr. Hinsdale says, had the unusual faculty and patience to set down the minute details

of cases as they came under observation. Dr. Rush's account, which is reproduced verbatim, reveals a remarkable parallelism between the epidemic of 1789-1790 and that of 1918-1919. It includes a classic description of the sneezing, hoarseness and sore throat; the sense of weariness, chills and fever, pains in the head and infection in the frontal sinus. "Many complained of a great itching in the eyelids. In some the eyelids were swelled. In others, a copious effusion of water took place from the eyes." Rush also describes mastoiditis, distressing cough and the final pneumonia, and the occurrence of secondary nervous and mental disturbances consequent on the disease.

Twenty-seven years after the epidemic described by Benjamin Rush, there occurred another epidemic which was described by Daniel Drake, who was acting as an army surgeon to two regiments of militia in camps when the influenza swept down from the "East to the frontier post in the Ohio Valley where he was stationed." He describes the way in which the disease first attacked the men in his camp, secondarily, the towns surrounding, and finally the scattered inhabitants of the country districts. "I need not give the history of any other prevalence," he says, "as this illustrates the most constant of the laws which govern influenza: first, its progressive extension from east to west; and second, its independence of all sensible conditions of atmosphere; third, its first outbreak in bodies of men, and compact settlements." Drake closes his account by mentioning the occurrence of purulent pleural effusions as the most serious sequelae.

In connection with these reports, we may point out that, allowing for the lack of knowledge of bacteriology and modern pathology, these early observers noted practically all of the important facts concerning this disease. Their reports are vital evidence of the importance of close, systematic observation in the practice of medicine.

Current Comment

ANOTHER WATER SUPPLY "ACCIDENT"

A recent report¹ of the typhoid outbreak at Lansing, Mich., in March, 1919, illustrates once more the necessity of caring for the surroundings of public water supplies from deep wells. The Lansing outbreak was apparently caused by leakage of sewage-contaminated ground water into the good water in the wells. It is stated that no thorough and regular investigations had been made of the lead joints between suction pipes and casings, and that the piping was under water much of the time. In March of last year, heavy rains caused the Grand River to rise eight feet, the pressure from this source forcing concentrated sewage into the sandy soil around the wells. An extensive outbreak of intestinal disturbance followed almost immediately, 3,000 cases of so-called water-borne dysentery being caused. Following this, eighty-two cases

1. Engineering News Record 84:92, 1919.

of typhoid developed, resulting in eleven deaths. This "accident," due to neglect of the surroundings of a good artesian water, is almost exactly similar to the extensive outbreak at Rockford,² eight years ago. Information about the cause of the Rockford outbreak and similar water-borne epidemics has been available for a number of years in the various technical journals dealing with water supply. It seems strange that such disasters can still occur, since every responsible engineer must be well aware of the necessity for safeguarding the casings and suction wells wherever a deep well supply is used as a drinking water source.

THE 1920 INFLUENZA

The outbreak of influenza in the United States which began about the middle of January has now progressed far enough for its main characteristics to be plainly seen. It is noteworthy that the death rates from influenza and pneumonia in the large cities were below the usual average all over the country from May, 1919, to Jan. 1, 1920. The first marked change seems to have occurred almost simultaneously in Kansas City and in Chicago, where the influenza-pneumonia rates rose sharply in the week ending January 17, although in Chicago an excess over the average was not reached till some days later. The maximum mortality in Chicago occurred in the week ending January 31, but in Kansas City the mortality reached its height a week later. New York, Washington, San Francisco, Milwaukee and St. Paul all showed an increase in the week ending January 24, and many other cities were added to the list in the following two weeks. The Census Bureau report for the week ending February 14 showed that thirty-two out of the thirty-six large cities reporting had a largely increased death rate from influenza and pneumonia as compared with the February weekly average in 1917. The same report states that the number of death claims per thousand policies in force (42, 300 and 241) in industrial insurance had increased in the annual rate from 10.3 for the week ending January 24, 10.9 for the week of January 31 and 13.0 for the week of February 7 to 14.1 for the week of February 14. The relative severity of the 1920 influenza is difficult to estimate correctly at this time. If it is possible to repeat in several well chosen localities the exact enumeration of morbidity and mortality secured in a few places by the U. S. Public Health Service in 1918, there will be better opportunity for a judgment on this point. It is worth noting, however, that in several cities, Milwaukee, Minneapolis and Kansas City, for example, the total death rate was considerably higher in the week ending Feb. 7, 1920, than it was at any time during the 1918 epidemic. In Chicago the death rate, while not as high as in October, 1918, rose to a point far above that reached during the 1889-1890 influenza outbreak. Although the total mortality in Chicago for the first half of January was considerably lower than the mortality for the average of the corresponding weeks of 1913-1917, the influenza in the last two weeks of the month brought the total January mortality to 5,149,

much the highest monthly mortality in the history of the city with the single exception of October, 1918, when influenza raged through the whole month. In Detroit, likewise, the epidemic has been severe. The weekly health reviews by the commissioner of health state that by the twentieth day of the epidemic there had been 1,161 reported deaths from influenza and pneumonia, as compared with 836 for the corresponding period in the 1918 epidemic. Up to the present writing the chief prevalence of the disease has been in the Middle West. According to the reports of the U. S. Public Health Service made by state health departments, Illinois has had the largest number of cases. Kansas, Wisconsin, Minnesota and California have also reported several thousand cases each. In the East, Connecticut and New Jersey had reported by January 31 a relatively large proportion of cases. It seems reasonable to suppose that most communities, at all events the larger cities and towns that have not already experienced an influenza outbreak in 1920, will have some recurrence of the disease. The impression seems to be in general that the disease is milder in its symptomatology and that the rate of incidence is considerably lower.

PHARMACY BY ACT OF CONGRESS

The school of political thought that holds to the *laissez faire* doctrine sometimes described as Manchesterism has always pooh-pooed the idea that it is possible to make men moral by statute. Should the present national experiment in prohibition be successful it will give the Manchester doctrine a body blow and do much to make "morality by act of Congress" an established fact. This same experiment is, apparently, bringing about even greater wonders. For, insolvable problems—as we have been led to believe—in the field of pharmacy have been solved within the short time that the Eighteenth Amendment to the Constitution of the United States has been in being. For years the gentlemen who have waxed rich and socially and politically powerful from the sale of those "patent medicines" whose most potent and powerful ingredient was alcohol have assured us with all the earnestness at their command that the alcohol in their nostrums was really but a regrettable incident in the manufacture. Alcohol has always been used in such cases, we were assured, for solvent, preservative or extraction purposes and occasionally "to prevent freezing"! Consider the case of a "patent medicine" more or less familiar to the readers of THE JOURNAL—"Wine of Cardui." This woman's tonic which, before the days of the Food and Drugs Act, was "a Certain Cure" and "Nature's Great Emmenagogue" later admitted (as per the law's requirements) the presence of alcohol to the extent of 20 per cent. Repeated and exhaustive experiments by some of the best chemists and pharmacologists in the country conclusively demonstrated that the alcohol was the most powerful and active drug in it. THE JOURNAL's first extended article on this product brought the claim from the manufacturers that no more alcohol was used than was "needed as a solvent and preservative" and the further declaration that they had "employed leading chemists who

2. Jordan, E. O.: The Rockford (Ill.) Typhoid Epidemic, J. Infect. Dis. 11: 21, 1912.

have sought widely for another preservative, but without success." In the court action that followed THE JOURNAL'S exposés the Wine of Cardui concern again emphasized its inability to diminish the amount of the alcohol. As the company's attorney said in his opening statement, Wine of Cardui had been submitted to one of the great chemists in the United States "for the purpose of ascertaining whether or not any other solvent or preservative could be used rather than alcohol." This great chemist "found that 20 per cent. of alcohol was the exact amount that would answer the purposes and that anything substantially beneath that amount would make the medicine spoil and would no longer act either as a solvent or as a preservative." "Wine of Cardui" continued to contain 20 per cent. of alcohol—the irreducible minimum, according to the manufacturers; an unnecessarily large amount, according to the medical profession. Then came national prohibition. Today Wine of Cardui contains 10 per cent. alcohol and its preservative powers have been fortified by the addition of benzoates. Verily, the wonders of science are as nothing to the marvels of legislation!

TISSUE CONSERVATION THROUGH THE ACTION OF QUININ

While there are numerous drugs and chemical substances that stimulate metabolism and lead to a breakdown of tissue and a corresponding waste of body material,¹ it is not easy to cite compounds that affect the organism in the direction of tissue conservation. One of the latter, however, is quinin. It has long been known that quantities of the drug too small to have marked pharmacodynamic effects may decrease the disintegration of nitrogenous compounds in the body. The output of urea is diminished after administration of the alkaloid to persons on a constant diet, without any impairment of absorption from the alimentary tract. It has even been suggested that the antipyretic action of quinin is in essence due to the lessening of metabolism and consequent diminution in the amount of heat liberated in the body. Whether or not the fall of temperature often induced by the drug is due to lessened heat production is not positively determined. Hence every evidence bearing on the effects of quinin is still of importance. When a bird produces eggs, it separates from itself a considerable amount of protein for the formation of the egg white and egg yolk. At the Station for Experimental Evolution at Cold Spring Harbor, N. Y., Riddle and his associates² have apparently demonstrated that the amount of albuminous substance expended by the body in egg production is decreased under the influence of quinin. In their experiments with it on ring-doves, less than the normal content of nitrogenous compounds was released by the albumin-secreting gland of the oviduct during egg production, thus furnishing an added illustration of the protein-conserving effect of the alkaloid, which is unique also in other ways.

1. Illustrations are given by Higgins, H. L., and Means, J. H.: *J. Pharmacol. & Exper. Therap.* 7:1, 1915.

Association News

THE NEW ORLEANS SESSION

The Scientific Exhibit

The Scientific Exhibit at the New Orleans session will be located on the third floor of the Hutchinson Memorial Building, the Medical Department of Tulane University. Ample space has been provided for exhibits in the large laboratories, while the halls afford abundant wall space for charts, diagrams, photographs and placards. The amphitheater on this floor is equipped with projection apparatus, screens, etc., and will be used for the demonstration of roentgenograms, lantern slides and moving picture films suitable for the Scientific Exhibit. If sufficient material is offered, a continuous program will be arranged for the four days of the session. Applications for space in the Scientific Exhibit or for assignment on the program of the moving picture exhibit should be sent at once to the Director of the Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago, stating the character of the exhibit, the amount of space or time required, and the name of the individual or institution wishing to make the exhibit. As space will be assigned shortly after March 1, applications should be made at once.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

State Society Meeting.—The Medical Society of the State of California will meet, May 11, 12 and 13, at Santa Barbara instead of at Delmonite, as at first planned. Headquarters will be at the Hotel Ambassador.

Physician Arrested.—Dr. Amos J. Landis of Chico has been arrested on a charge of violating the state drug laws by the illegal sale of narcotics.—A. F. Francis of Oroville was arrested on the charge that he is not a physician and is practicing without a license.

Personal.—Dr. James H. Barr, Marysville, health officer of Yuba County, and Dr. A. L. Miller, health officer of Yuba City, have been appointed assistant collaborating epidemiologists by the state board of health.—Dr. Walter M. Dickie, Los Angeles, has been appointed director of the bureau of social hygiene of the state board of health.

Illegal Practitioner Charged with Manslaughter.—Mrs. Gertrude Steele, a naturopathic physician of Venice, is charged with manslaughter and with practicing outside the limits of her certificate. She was arrested following the death of her son-in-law, George A. Blaha of Venice, who was treated by Mrs. Steele with a freckle lotion which is said to have caused his death.

Bureau of Child Hygiene.—The bureau of child hygiene of the state board of health became an entity following the passage of a law at the last legislature. Dr. Ethel M. Watters, San Francisco, who formerly had charge of the juvenile court children in San Francisco and for two years was sanitarian of the social hygiene bureau of the state board of health, was appointed director.

Diploma Lost.—Early in January, 1920, a diploma issued to Dr. William Hammond Worley by the Hahnemann Medical College and Hospital, Chicago, April 26, 1900, was reported to have been lost by the Railway Express Company in Los Angeles. Officers of all state licensing boards are requested to be on the lookout for such a diploma, since it may have been stolen.

Sun Cult Leader Arrested.—Ottoman Zar-Adusht Hanish, self-styled "little master" of the Mazdaznan cult of sun worshippers, Los Angeles, has been arrested by the Board of Medical Examiners on charges of grave offenses against

minor children. In 1913, Hanish was convicted in the federal district court of sending indecent matter contained in his cult book, "The Inner Circle," through the mails, and was sentenced to six months in jail. April 25, 1918, Hanish was charged with practicing medicine without a license, at which time he vanished.

League for Conservation of Public Health.—The league will survey all the hospitals in the state and will soon promote a state conference of hospitals to discuss problems which will be brought up as a result of the survey. Only those hospitals, whether large or small, which have been adhering to a high standard of service, will be included in membership. The third annual meeting of the league was held in San Francisco, Dec. 29, 1919, and the following officers were elected: president, Dr. Dudley A. Smith, Oakland, and vice president, Dr. Granville McGowan, Los Angeles.

COLORADO

Social Service at University.—The Association of Collegiate Alumnae has taken charge of the medical social service of the University of Colorado dispensary and clinic, Denver, has organized a corps of volunteers for such service, and has placed in charge of the social service, Miss Madeline C. Ridgeway, formerly of Chicago.

Influenza.—The University of Colorado, Denver, which was closed for two weeks on account of an epidemic of influenza, reopened February 16.—The *Denver Post* announces that it will pay \$25,000 to the physician finding a cure for influenza, the money to be paid after the cure has been approved by the Rockefeller Institute for Medical Research and Johns Hopkins University.

Tuberculous Persons Should Not Leave Home.—The Denver Anti-Tuberculosis Society has issued a leaflet entitled "Why Tuberculous Persons Without Funds Should Not Leave Home." This leaflet gives a consensus of opinion of the tuberculosis workers of Denver in regard to sending indigent tuberculous sufferers West. It is estimated that several hundred tuberculous persons without funds come to Denver every year and arrive almost penniless and without provision for their needs. Since Colorado has no state sanatorium and Denver no municipal sanatorium, the care of such persons is limited to a few free private sanatoriums which are continuously overtaxed. The society urges that states throughout the country plan definite programs to retain their indigent tuberculous patients, giving them effective treatment in state sanatoriums or in their own homes.

ILLINOIS

Sanatorium Changes Hands.—The Mennonite Sanitarium Association has purchased the Kelso Sanitarium property, Bloomington, and will conduct its hospital operations on an enlarged plan.

More Money for Speedway Hospital.—On February 20, the United States Senate adopted an amendment to the urgent deficiency bill adding \$500,000 to the limit of cost of the Speedway Hospital.

Personal.—Dr. William F. Carroll, New Holland, who has been seriously ill with influenza has recovered.—In the case of Dr. Pierre J. Fullerton, Dupon, against St. Clair County in which he sought to collect \$350 alleged to be due him for treating indigent smallpox patients, the jury returned a verdict in favor of the county on the ground that Dr. Fullerton had not been authorized to treat the patients.

Chiropractor Arrested.—According to report, Frank D. Whittenberg, a chiropractor living at Mt. Carmel, was arrested for practicing medicine without a license. Whittenberg claims that State's Attorney Phipps of Wabash County told him to go ahead and practice without a license. Whittenberg is now reported to have not only discontinued practice but also to have sold his office fixtures and left the state.

Forged Prescriptions for Whisky.—A recent investigation by the Illinois Department of Registration and Education shows that persons in Chicago are writing prescriptions for whisky on regular prescription blanks and forging the signature of Dr. John W. Sarpalius, a licensed physician in Illinois. Dr. Sarpalius left Illinois some months ago and now resides in Alden Station, Pennsylvania. On leaving Chicago, he left behind a number of prescription blanks with his name and address printed thereon. These blanks were taken from his Chicago office and are now being used extensively for whisky prescriptions. An inspector picked up thirty-four in two drug stores in Chicago. Each called for

a pint of whisky for use "as directed." The department has no jurisdiction over the writing of whisky prescriptions, but they were turned over to Major Dalrymple in Chicago for investigation.

Chicago

Personal.—Dr. Ludvig Hektoen has been elected an honorary member of the Pathological Society of Philadelphia.

Midwife Fined.—Mrs. Anite Salvino, a midwife, was fined \$25, February 19, for failure to apply silver nitrate to the eyes of a baby in her care.

Municipal Sanatorium.—The January issue of the *Bulletin of the City of Chicago Municipal Tuberculosis Sanatorium* contains a detailed description of the vocational school for the tuberculous, by Dr. John Dill Robertson, profusely illustrated.

Institute of Medicine Meeting.—A meeting of the Institute of Medicine of Chicago will be held March 5, at the City Club, 315 Plymouth Court at 8 p. m. Prof. James R. Angell of the National Research Council will speak on "The Organization of Research in a Democracy."

Reception and Dinner to Admiral Braisted.—Surg.-Gen. William C. Braisted of the United States Navy, President-Elect of the American Medical Association, will read a paper before the Chicago Medical Society at its meeting, Wednesday evening, March 3. A reception and dinner at the Palmer House at 6 p. m. will be tendered him previous to the meeting to which all members of the Association are cordially invited.

Fraternity Dinner.—The Alpha Omega Alpha Honorary Medical Fraternity announces that the annual dinner of the three Chicago chapters located respectively at the University of Illinois, University of Chicago, and Northwestern University, will be held March 1, at the Congress Hotel, at 6:30 p. m. Among the speakers will be Dean Irving S. Cutter, Omaha, of the University of Nebraska, Dean John L. Heffron, Syracuse, of Syracuse University and Dr. William W. Root, Slaterville Springs, N. Y.

Druggist Arrested for Practicing Medicine.—Joseph P. Baltrenas who owns a drug store at 1705 South Halsted Street, is reported to have been arrested recently for practicing medicine without a license and was fined \$200 and costs. Baltrenas had in his possession a license as a physician issued by the state board of health in 1916, but the name of the physician had been erased and that of Baltrenas substituted. An inspector of the Department of Registration and Education recognized that it was fraudulent. It later developed that the license had been stolen from the office of Dr. Ralph Waldo Petersen. Baltrenas claimed he had paid a certain "senator" \$3,500 for the license.—Three other cases against Baltrenas will be heard in March; one for buying a license, one for aiding and abetting in the purchase or sale of a license and still another for practicing under a license fraudulently obtained. The maximum fine for each offense is \$200 or one year in jail, or both.

IOWA

New Officers.—Northwest Iowa Medical Society at its annual meeting in Sheldon elected Dr. Louis L. Corcoran president and Dr. Jay M. Crowley secretary, both of Rock Rapids.—Hardin County Medical Society at its annual meeting at Eldora elected Dr. J. Willard Caldwell, Jr., Steamboat Rock, president; Dr. William H. VanTiger, Eldora, vice president; Dr. William E. Marsh, Eldora, secretary, and Dr. Clarence M. Wray, Iowa Falls, treasurer.

KANSAS

Personal.—Dr. Louis B. Gloyne, who has been serving as health director of Kansas City, has been made city physician.

New Officers.—Brown County Medical Society held its annual meeting in Horton, January 6, and elected Dr. Roscoe T. Nichols, Hiawatha, president; Dr. James S. Rushton, Morrill, vice president, and Dr. James M. Robinson, Hiawatha, secretary-treasurer.

Venereal Disease Activities.—During the period from July 1, 1918, to Dec. 30, 1919, there were reported to the division of venereal disease of the state board of health 3,311 cases of gonorrhea, 1,405 cases of syphilis and fifty-four cases of chancroid. Treatment has been provided through clinics located at Wichita, El Dorado, Topeka, Lawrence, and Rosedale, and a clinic is expected to be in operation this month at Kansas City. At these clinics 537 cases of gonorrhea, 745 cases of syphilis and twenty-four

cases of chancroid have been treated. In connection with the University Medical School at Rosedale, a public health laboratory has been maintained which has furnished an average of 500 Wassermann examinations a month since its establishment, Jan. 1, 1919. At the quarantine camp established at Lansing, twenty-one men and 340 women were detained in 1918, 157 men and 258 women in 1919.

KENTUCKY

Libraries Consolidated.—The libraries of the medical department of the University of Louisville and of the Jefferson County Medical Society have been consolidated and will be housed at the medical college.

Eye and Ear Men Elect.—The Louisville Eye and Ear Society at its annual meeting, January 8, elected Dr. Claude T. Wolfe, Louisville, president; Dr. Albert L. Bass, Louisville, vice president, and Dr. Walter Dean, Louisville, secretary-treasurer.

Contract Let for Government Hospital.—The Dawson Springs Construction Company has received the contract for the construction of three main buildings of the \$1,500,000 governmental hospital at Dawson Springs. The hospital will be used to take care of discharged soldiers, sailors and marines. This contract is for the erection of a hospital building, an administration building and a nurses' home and the combined cost will be \$680,666.

Personal.—Col. Dunning S. Wilson has been discharged from the Medical Corps, U. S. Army, and has returned to Louisville.—Dr. Randolph Dade, Jr., has succeeded Dr. John W. Harned, resigned, as health officer of Hopkinsville.—Dr. Daniel V. Bentley, Whitesburg, is reported to be critically ill with cerebrospinal meningitis.—Dr. Lester A. Crutcher, Louisville, has resigned to accept a position with the Kentucky State Board of Health, and has been succeeded by Dr. Louis A. Mehler, Louisville.—The Jefferson County court jury has refused to indict Dr. Christopher G. Schott, Louisville, who was charged with murdering his office assistant.

Nutrition Survey.—The big gray automobile known as the Child Welfare Special which the Children's Bureau of the United States Department of Labor is using to bring the welfare message to babies in villages and on farms, has been cooperating in the nutrition survey in one of the rural sections of Kentucky. The county selected was in the mountain district, 250 cases were studied, and it is hoped that the examinations will reveal the causes responsible for the malnutrition prevalent in this area. The information was obtained by a house-to-house canvass and the examinations were made by the staff of the Child Welfare Exhibit in an automobile truck fitted as a model well-baby clinic with a government physician and nurse in charge. The car is parked in a central location, usually near a court house, town hall, lodge hall or woman's club. One family at a time is received in the car, the health history of the family is secured, each child is examined, weighed, and measured, and advice is given to the mother in hygiene matters.

LOUISIANA

Ground Broken for Hospital.—Construction work on the new Presbyterian Hospital, New Orleans, has been begun. The new building will be three stories in height, but eventually other stories, up to ten, will be added.

Personal.—Dr. Joseph G. Stullb, New Orleans, visiting physician to the Isolation Hospital has resigned.—Dr. Mayer A. Newhauser, New Orleans, has succeeded Dr. G. C. Chandler as president of the board of health of Shreveport.

Laboratory Item.—Dr. Abraham L. Metz, city chemist, has tendered the use of his new chemical laboratory to the city of New Orleans, and it was formally dedicated to the city's use, February 1. The plant represents an outlay of \$15,000 and includes a library of 1,000 volumes.

New Officers.—At the annual meeting of the Rapides Parish Medical Society held at Alexandria, February 5, Dr. Paul K. Rand, Alexandria, was elected president and Dr. George Antony, Alexandria, secretary-treasurer.—Calcasieu Parish Medical Society at its annual meeting, Dec. 31, 1919, adopted a resolution authorizing appointment of a committee to enter into negotiations with the state board of health regarding the establishment of a public laboratory in Lake Charles. Dr. John G. Martin, Lake Charles, was elected president, Dr. Cecil R. Price, De Quincy, vice president, and Dr. Dempsey C. Iles, Lake Charles, secretary-treasurer.

MASSACHUSETTS

Personal.—Dr. Fred D. Jones, Springfield, has been appointed medical examiner (coroner) of the second Hampden, district, succeeding Dr. Edward J. Mahoney, Springfield, resigned.—Dr. Frederick R. Barnes, Jr., Fall River, has been appointed associate medical examiner (coroner) of the third Bristol district, succeeding Dr. John H. Gifford, resigned.—Dr. Llewellyn H. Rockwell has been appointed acting superintendent of the Long Island Hospital during the absence of Dr. Charles E. Donlan.—Dr. Samuel B. Woodward was reelected vice president of the Worcester Chamber of Commerce at its meeting, January 20.—Dr. William T. Sedgwick, senior professor in the Massachusetts Institute of Technology and head of the department of biology and public health, will be the first exchange professor with the universities of Cambridge and Leeds.—Dr. Oren M. Deems, Springfield, is reported to be seriously ill with pneumonia.

MICHIGAN

Personal.—Dr. Albert C. McLeod, Calumet, has just returned after five years' service in the Royal Army Medical Corps.—Dr. E. Charles Hughes, Armada, has been appointed superintendent of the Burley Hospital, Almont.

Industrial Earnings.—According to the published report made at the annual meeting of stockholders, Parke, Davis & Co. earned net profits of \$4,293,591 for 1919. The sales for the year were approximately \$25,000,000. The gross profits were \$6,604,702 and of this \$2,000,000 was reserved for excess profits and income taxes and \$194,845 for depreciation.

Venereal Disease Clinics.—Dr. Garner M. Byington, Charlotte, director of the bureau of venereal disease, announces that Battle Creek, Lansing, Kalamazoo, Jackson, Flint, Bay City, Saginaw, Detroit and Ann Arbor are operating venereal disease clinics in close cooperation with the bureau and that similar clinics will soon be established in Grand Rapids and Muskegon.

Cancer Publicity.—The entire December number of *Public Health*, the monthly news bulletin of the Michigan Department of Health, was devoted to cancer. The number was prepared in response to a belief that public sentiment must be thoroughly aroused and organized, and that scientific data on the cancer problem must be given to the public if results are to be obtained in the campaign for the eradication of cancer.

MINNESOTA

Personal.—Dr. Mabel S. Ulrich, Minneapolis, has been appointed health director of the northern division of the American Red Cross.

Decline in Mortality.—The division of public health of the board of public welfare, Minneapolis, in its last bulletin gives a résumé of the decline in the mortality from certain diseases since 1890. The deaths from typhoid fever per hundred thousand of population between 1891 and 1900 numbered 49; and in 1919, about 4; the deaths from diphtheria per hundred thousand of population from 1890 to 1899 averaged 0.43, compared to 0.165 in 1919; the deaths from tuberculosis per thousand population from 1890 to 1899 were 1.28, and in 1919, 0.97; and the death rate of infants under 1 year, which from 1900 to 1909 was 88.2 per hundred thousand, dropped in 1919 to 66.5.

MISSISSIPPI

Influenza.—On account of the spread of influenza all of the rural schools near Purvis, the town schools, and the Lamar County Agricultural School have suspended indefinitely and all public meetings have been interdicted.—The schools, churches and other public places of Hazlehurst and Wiggins have been closed for the same reason.

Home for Feeble-minded.—The Mississippi society for mental hygiene is urging the passage of a bill calling on the legislature for an appropriation of \$200,000 with which to prepare and maintain a home for feeble-minded for the next two years. There are at present 1,317 feeble-minded persons in the state, 205 of whom are in state insane hospitals, 90 in orphanages, 10 in the industrial training school, 14 in the state institution for deaf and dumb, 345 in county jails, 214 on county poor farms and 439 in the state penitentiary.

Mental Deficiency Survey.—The report of the Mississippi Mental Hygiene Commission to the governor, January 7, after an exhaustive report on present conditions regarding mental

deficiency in the state, recommends the establishment and organization of a state colony and training school for the feeble-minded; the organization of special opportunity schools as a part of the public school system, these schools to emphasize training of the nervous system through the hands; the organization of mental clinics; at the disposition of every school, court and social agency someone specially trained in medical and social service as related to mental deficiency; the complete divorce of hospitals of the insane and the colony for the feeble-minded from partisan politics and their organization under a state psychiatrist as director, and finally a system of state registration and state supervision of all mentally defective individuals.

MISSOURI

Graduate Instruction in Pediatrics.—Washington University, St. Louis, has established a course of graduate instruction in pediatrics to begin April 5. Particulars of this course may be obtained on addressing the dean of the school.

Semicentennial Ceremonies.—Jackson County Medical Society will honor with a dinner at the City Club, Kansas City, March 4, members who have practiced medicine a half century. Five members will be thus honored: Brig-Gen. Jefferson D. Griffith, Kansas City, who graduated from New York University Medical College in 1870; Dr. John C. Rogers, Kansas City, an alumnus of Washington University Medical School, St. Louis, in 1865; Dr. John Wilson, Kansas City, a graduate of the same school in 1866; Dr. John S. Mott, Kansas City, a graduate of the University of Michigan, Ann Arbor, 1867, and Dr. Thomas R. Thornton, Lees Summit, a graduate of Washington University, St. Louis, in 1868.

Personal.—Dr. Owen P. McPherson, Kansas City, has recently received the medal of the first order of St. Sava from the Serbian Government. Dr. McPherson was assigned to the American Military Red Cross Hospital, No. 5, in Serbia and afterward established two hospitals. —Dr. Robert Vinyard, St. Louis has been appointed assistant physician to the Frisco Hospital, Springfield. —Dr. George M. Boteler, St. Joseph, has been appointed assistant health officer of St. Joseph and placed in charge of the emergency and influenza hospital. —Dr. William D. Fulkerson, Clinton, for thirteen years local surgeon of the Rock Island System, has resigned and expects to retire to a farm near Catesville. —Dr. Fayette C. Ewing, Webster Groves, has moved to Alexandria, La., and has been appointed chief of the eye, ear, nose and throat department of the U. S. Public Health Hospital at that place.

MONTANA

Western Montana Physicians Elect Officers.—At the annual meeting of the Western Montana Medical Society held in Missoula, Dr. Harry B. Farnsworth, Missoula, was elected president; Dr. John P. Ritchey, Missoula, vice president, and Dr. James D. Hobson, Missoula, secretary-treasurer.

Personal.—Dr. Roscoe C. Main, formerly of Marquette, Mich., has succeeded Dr. Louis W. Allard, resigned, as health officer of Billings and Yellowstone County. —Dr. Frank D. Pease, Missoula, has been appointed full-time health officer of Missoula County and will assume his new duties, April 1.

Public Health Hospital for Mental Diseases.—A hospital for the treatment of mental diseases is being opened at Fort Harrison, Helena, by the United States Public Health Service. Dr. Arthur S. Pendleton is the officer in charge. The hospital will not be an insane asylum but is designed to care for men who have been mentally incapacitated in war service.

NEBRASKA

Meningitis at College.—Doane College and other schools in Crete have been closed and public gatherings prohibited because of an outbreak of cerebrospinal meningitis.

New Officers.—At the annual meeting of the Dodge County Medical Association, held in Fremont, January 1, Dr. Byron B. Hauser was elected president, Dr. James C. Agee, vice president and Dr. Grant S. Reeder, secretary-treasurer, all of Fremont.

Personal.—Dr. Jerome G. Pace, Lincoln, has been appointed superintendent of the Modern Woodmen of America Sanatorium, Colorado Springs, succeeding Dr. James A. Rutledge, deceased. —Dr. Floyd C. Dean, Hastings, formerly superintendent of the sanatorium at Hastings, has been appointed superintendent of the Kansas Sanatorium, Wichita, succeeding Dr. Robert L. Stokes, resigned.

NEW JERSEY

Changes in Sanatorium Management.—Commissioner Burdette G. Lewis of the Department of Institutions and Agencies, has made the following recommendations to improve conditions at the New Jersey Sanatorium for Tuberculous Diseases, Glen Gardner: a roentgen-ray examination of every patient admitted to the institution; the purchase of strictly fresh eggs and more careful adherence to the dietaries suggested by this department and approved by the federal bureau of foods and drugs; the employment of a trained social worker; the enlargement of the institution to accommodate enough patients to reduce the per capita cost of medical, scientific and social work, and to provide home-like surroundings including sitting rooms and play rooms for children.

NEW YORK

Mental Clinic Established.—The American Red Cross and health department of Plattsburg have started a mental clinic in that city under the charge of Dr. John R. Ross, medical superintendent of the Dannemora State Hospital.

Tuberculosis Survey.—A summary of the clinics which have been held in Oneida County under the auspices of the state department of health, by the State Charities Aid Association, shows that 1,287 patients were examined, of whom 214, or 16.6 per cent., were found positive, 390, or 30 per cent., suspicious, and 683 negative.

Tuberculosis Association Bulletin.—The first issue of the *Bulletin of the New York Tuberculosis Association, Inc.*, has made its appearance. It is an eight-page periodical having for its purpose the dissemination of knowledge for the information of all those interested or engaged in the fight against tuberculosis in New York City and elsewhere. Mr. David Ryan is managing editor.

Personal.—Dr. Reeve B. Howland, Elmira, has been reappointed health officer of Elmira for a term of four years. —Dr. Frederick M. Meader, Albany, director of the division of communicable diseases in the state board of health, has been granted an indefinite leave of absence in order to accept an appointment as surgeon in the United States Public Health Service. Dr. Edward S. Godfrey, Jr., has been appointed acting director of the division in the place of Dr. Meader.

New Organization to Fight Quackery.—A national cooperative service, under the name of the Doctors Service Corps, and including physicians, surgeons and dentists, has been organized for the detection and punishment of "dead beats," and as an intelligence service to operate against frauds. The movement is endorsed by Prof. Irving Fisher of Yale, Major A. R. Crane, formerly chief dental surgeon to U. S. Army General Hospital No. 1, and Herbert D. Brown, chief of the Bureau of Efficiency, Washington, D. C.

New York City

Meeting in Memory of Sir William Osler.—A meeting in memory of Sir William Osler is scheduled to be held February 28, at 8:30 p. m., in the New York Academy of Medicine.

School Hygiene.—The bureau of public health education, department of health has instituted publication of a monthly pamphlet, *School Health News*, for the information of school teachers.

Personal.—Dr. T. Mitchell Prudden, who has been a member of the Public Health Council since its inception, was recently reappointed by Governor Smith for a term of six years. —Dr. Elbert M. Somers, Brooklyn, has been appointed deputy medical examiner of the bureau of deportation by the State Hospital Commission.

Seamen's Service Center.—The Seaman's Service Center, operating under the direction of the Surgeon-General of the United States Public Health Service in cooperation with the Red Cross and volunteer agencies, was recently established for the purpose of assisting merchant seamen entering the port of New York. The center will be conducted as a clearing house for the sick, disabled and needy sailors of the merchant fleets of the world.

OHIO

Verdict for Physician.—In the case of Ralph Meyers against Dr. Corwin T. Hill, Akron, in which the plaintiff sought to recover \$25,000 on claims that the defendant was

negligent in treating a fracture of the leg, a verdict in favor of the defendant was returned by the jury after a fifteen minute session.

County Health Commissioners.—Of the eighty-eight counties of the state, fifty have already organized under the Griswold act, and thirty-nine health commissioners have been appointed, twelve of whom are to serve full time. Twenty-five of the fifty counties have made provision for a public nurse, and thirty nurses have already been named.

Chiropractors Fined.—It is reported that Mike Klotz, a chiropractor residing at Akron, was fined \$200 and costs in the municipal court of Cleveland for practicing medicine without a license.—A report also states that A. M. Hoch, chiropractor at Cleveland, was fined \$500 and costs, and that M. Pottgeiser, a chiropractor of Cleveland, was fined \$100 and costs on a similar charge.

Prosecutions During 1919.—A letter received from Dr. Herbert M. Platter, secretary of the Ohio state medical board, states that during 1919 thirty-two individuals were convicted for the illegal practice of medicine and four for the illegal practice of midwifery, and the certificates of seven physicians were revoked and one certificate was suspended. Fifteen other individuals against whom cases were pending left the state and for that reason were not brought to trial.

Personal.—Dr. Benjamin I. Harrison, Cleveland, has been awarded a traveling fellowship for one year by Western Reserve University. Dr. Harrison saw service with both the British and American Expeditionary Forces during the world war. He will initiate his studies at the University of Oxford, England.—Dr. William S. Warren, Jacobsburg, was seriously injured by the overturning of his automobile near Businessburg, February 3.—Dr. Chester M. Peters, Canton, has been appointed health commissioner of Stark County.

Hospital Items.—Plans for the \$500,000 hospital to be erected at the Masonic Home have been approved by the trustees.—The plan, which has been under consideration for several years, for the erection of a joint tuberculosis hospital by the counties of Muskingum, Fairfield, Perry, Licking and Coshocton, has been abandoned so far as the Muskingum County commissioners are concerned.—The Massillon State Hospital has been granted an appropriation of \$130,000 for a new hospital building and an industrial building. The present industrial building will be converted into a cottage. The capacity of the hospital will thus be increased so that 130 additional patients can be accommodated.

PENNSYLVANIA

Conference of Industrial Physicians and Surgeons.—The state department of labor and industry will convene the tenth conference of industrial physicians and surgeons in the state capitol, Harrisburg, March 25.

Philadelphia

Drive for St. Agnes' Hospital.—For the first time in its thirty-two years of existence, St. Agnes' Hospital will appeal to the public for funds in a drive for \$500,000 to be inaugurated March 15.

Osteopaths Lose Test Case.—The first step in a test case brought to determine whether or not practitioners of osteopathy may prescribe and administer drugs to patients was lost by the osteopaths when Judge Martin in Quarter Session Court refused to grant a new trial to Philip S. Dailey and fined him \$50 and the costs of prosecution.

Personal.—Dr. Robert N. Keely has been appointed surgeon of the Philadelphia Nautical School's schoolship *Annapolis*.—Dr. Max R. Gabrio has been appointed chief resident physician at the Philadelphia Hospital for the Insane at Byberry to succeed Dr. James Allen Jackson, resigned.—Dr. Edgar Fahs Smith was unanimously offered the position of provost emeritus of the University of Pennsylvania by the board of trustees.—Dr. John F. X. Jones has been appointed a member of the surgical staff of St. Agnes' Hospital.

Influenza Fund.—The city council has passed a general appropriation bill by which \$50,000 will be available for combating influenza or for use in any other health emergency. The director of public health and charities will expend the money, subject to approval of the mayor, president of council and chairman of the finance committee. The latest report indicates that influenza is decreasing: the number of persons taken ill in the twenty-four hours ending at

noon February 19 was 176 as compared with 219 on the preceding day, with 100 deaths from influenza, pneumonia and complications.

CANADA

Medical Building for University.—The United States Consul at Calgary, Alta., reports that a new medical building to cost \$750,000 is to be erected for the University of Alberta. The plans have already been prepared and the construction will be commenced as soon as weather conditions permit.

Disease Record of Ontario.—There were almost 2,000 fewer deaths from communicable disease in Ontario during 1919 than in the previous year. Although more than 3,000 cases of smallpox were reported only nine deaths were recorded. Diphtheria caused 428 deaths and tuberculosis showed a slight increase, 2,234 cases and 1,722 deaths, as compared with 2,122 cases and 1,359 deaths in 1918.

Mental Hygiene Survey.—The Canadian National Committee for Mental Hygiene which was organized in April, 1918, has already conducted mental hygiene surveys in British Columbia, Manitoba, and Guelph, Ont. Governmental requests have been made for surveys during 1920 by the provinces of Alberta and New Brunswick, and the cities of Fort William and Port Arthur, Ont., while surveys are now in progress in Toronto and Ottawa, Ont., and Montreal, Que.

Postgraduate Course in Public Health Nursing.—In cooperation with the Victorian Order of Nurses and the public health, charitable and philanthropic organizations of Halifax and Dartmouth, Dalhousie University has inaugurated a course in public health nursing limited to graduate nurses. The Nova Scotia branch of the Canadian Red Cross Society has provided twenty scholarships of a value of \$200 each. Lectures will be given chiefly by members of the medical faculty, and will deal with every phase of public health nursing. These courses will be augmented by eighteen hours of field work each week in social service, prenatal hygiene, infant welfare and school medical inspection service, by attendance at public clinics and by visits to all hospitals, industrial schools and health and social centers in Halifax. Upon successful completion of the full course of six months, a certificate of proficiency will be awarded to candidates.

GENERAL

Duty on Scientific Apparatus.—The Senate Committee on Finance has approved the bill placing a duty of 45 per cent. on imports of surgical and scientific instruments and laboratory glassware. There was no opposition to this bill before the committee.

New England Medical Women Elect Officers.—At the annual reunion and banquet of the Medical Women of New England, held in Boston, January 17, Dr. Agnes C. Viotor was reelected president; Dr. Margaret L. Noyes Kleinert, vice president; Dr. Alice H. Bigelow, secretary, and Dr. Isabel D. Kerr, treasurer, all of Boston.

Transportation for Railroad Surgeons.—Physicians who act in a professional capacity for railroads will continue to have the privilege of free railroad transportation. The clause in the railroad bill as it passed the House of Representatives, which would forbid free transportation to physicians, has been eliminated by the conference committee.

Hospital Society Enlarged.—The National Methodist Hospital Association at its meeting in Chicago, February 12, voted to include homes for aged and for dependent children in its organization. Plans for cooperation with the inter-church world movement were discussed, giving over an item of \$100,000,000 in the budget for Methodist hospitals. Mr. E. S. Gilmore, superintendent of the Wesley Memorial Hospital, Chicago, was reelected president, and M. C. England, Cleveland, vice president.

Board for Ophthalmic Examination.—The next examination of the American Board for Ophthalmic Examinations will be held in New Orleans, April 26, at the time of the meeting of the American Medical Association. Applications and necessary credentials of candidates who desire to take the examination and obtain the certificate of the board should be in the hands of the secretary, Dr. William H. Wilder, 25 East Washington Street, Chicago, at least sixty days before the time set for the examination.

Health Work in Colleges and Universities.—In connection with the annual Conference on Public Health and Legislation called by the Council on Health and Public Instruction of the American Medical Association at the Auditorium Hotel,

Chicago, on March 4, 1920. Dr. John Sundwall, university health officer for the University of Minnesota, and Dr. Warren E. Forsythe, director of the university health service of the University of Michigan, have issued a call for all persons interested in health work in colleges and universities to attend a special meeting to be held at some convenient time during the conference to discuss special features of such work and possibly to effect an organization and arrange for meetings in the future. The time and place of the meeting will be announced at the conference.

Appropriations for Public Health Service.—In the emergency deficiency bill which has just passed the Senate, there is an appropriation of \$3,000,000 for medical, surgical and hospital services for war risk insurance patients of the Public Health Service. The expenditure of this money is made immediately available to care for the work of the Public Health Service in behalf of former service men of the Army and Navy. There is also included in this bill provision for the final purchase of the Broadview Hospital—Speedway—at Chicago, Ill. This hospital will be used by the Public Health Service in the care and treatment of war risk insurance patients. Three million dollars has been appropriated heretofore for the purchase of this hospital and an additional sum of \$500,000 is necessary to complete the construction of the hospital and make it meet the needs and purposes of the Public Health Service.

Philippine News.—The municipal council of Manila has approved an appropriation of 25,000 pesos (about \$12,500) to furnish free of cost condensed milk to indigent children during the year 1920.—There has been held recently at Batangas, the capital of the province of the same name, the meeting of the physicians of the twentieth sanitary district. The district sanitary director, Dr. José M. Raymundo, presided, and the meeting was attended by some of the most prominent Filipino physicians, including the director of public health, Dr. V. de Jesús, Drs. P. Gabriel and J. B. Cabarrús.—Plans are being made for the construction of a municipal hospital at Tondo at an estimated cost of 1,000,000 pesos (about \$500,000).—The following appointments have been announced: Dr. José Avellana Basa to be physician in chief of the Culión leper colony; Dr. Guillermo S. Sisón to be president of the thirteenth sanitary district division of Pangas; Dr. Fernando Calderón to be member of the board of trustees of the University of the Philippines, and Drs. José P. Bantug, Otto Schobl and Proceso Gabriel to act as a committee to report on the convenience and mode of enforcing anticholera vaccination in the Philippines.

The Dye Industry Bill.—Physicians, as well as chemists, are interested in the action of the Senate Committee on Finance in favorably reporting the dye industry bill. This is due to the fact that the manufacture of synthetic drugs is directly connected with the dye industry. The bill places import duties on dyes and an embargo on their importation, in order to encourage American laboratories to build up an industry which will be able to compete with the German monopoly heretofore dominating in the manufacture of synthetic drugs. The bill has already passed the House of Representatives. It provides a tariff of 30 per cent. on acetanilid suitable for medicinal use, acetphenetidin, acetyl-salicylic acid, antipyrin, benzaldehyd, benzoic acid, betanaphthol, phenolphthalein, resorcin, salicylic acid and its salts, salol and other medicinals. The subcommittee held extensive hearings covering a period of several weeks, and important statements on the subject of the development and production of synthetic drugs by American laboratories were made by Dr. Marston T. Bogert, professor of organic chemistry of Columbia University, New York, and Dr. Julius Stieglitz, chairman, department of chemistry, University of Chicago.

Decennial Pharmacopoeial Convention.—The United States Pharmacopoeial Convention has issued the call for its tenth decennial meeting at 10 a. m., May 11, in Washington, D. C., at the Hotel Willard. One of the first and most important activities of the convention will be the election of fifty delegates who will constitute a committee on revision, to which will be assigned the task of determining the general principles to be followed in compiling the tenth revision of the pharmacopoeia. The United States Pharmacopoeial Convention is a corporation constituted of delegates elected by a number of organizations associated for the purpose of revising the United States Pharmacopoeia every ten years. The interests of practitioners of medicine are conserved by delegates from the American Medical Association, the state medical associations, the medical colleges and the medical

departments of the U. S. Army, U. S. Navy and U. S. Public Health Service. Each of these organizations should promptly select three qualified and competent delegates who will attend the convention and take active part in framing its policies. Because of the importance of the work and because of the great responsibility it entails, the medical profession should be properly represented. Forms for certifying the delegates to the convention are to be obtained by addressing Dr. Noble P. Barnes, Arlington Hotel, Washington, D. C. These forms should be properly executed and the delegates reported to Dr. Barnes at least six weeks before the date set for the convention.

Legislation for Physical Education.—A bill for the promotion of physical education through cooperation of the federal government with the states has been introduced by Congressman Fess of Ohio. It provides for the employment of supervisors and teachers of physical education, including medical examiners and nurses. The work is to be conducted under the direction of the National Bureau of Education and the Public Health Service. The bill appropriates \$10,500,000 for 1921, and \$1 per year thereafter for each child of school age, the money to be apportioned to those states which shall appropriate an equal amount. Its provisions include a comprehensive course of physical activities, periodical physical examination, health supervision of schools, and schoolchildren; practical instruction in the care of the body and in the principles of health. The bill also provides for the establishment in the Public Health Service of a division of child hygiene. This bureau is to be in the charge of a commissioned officer of the Public Health Service who shall select other employees to assist him in his duties. These duties shall be to study and investigate the problems of child hygiene, to cooperate with state boards of health in medical research and practical administrative demonstrations relating to the health of women, children and to child bearing, and shall cooperate with the children's bureau of the bureau of education in matters relating to health conservation of children and mothers. An elaborate plan for cooperation with state authorities is formulated in the measure.

FOREIGN

Lister Memorial Institute.—The project which originated before the war for the establishment in Edinburgh of a memorial to the late Lord Lister has been revived. The memorial is to take the form of a scientific teaching and research institute under the auspices of the University of Edinburgh, the Royal College of Physicians and the Royal College of Surgeons of Edinburgh.

Statistics on Venereal Diseases in Germany.—The minister of the interior sent a questionnaire to all the physicians in Germany asking for the number of cases of venereal diseases in their charge between Nov. 15 and Dec. 14, 1919. The names of the patients were to be written on a perforated slip accompanying the questionnaire, but this was to be torn off and retained for the writer's information if need arises later.

Insane Aliens in Switzerland.—At the recent semiannual meeting of the Société des médecins aliénistes suisses a resolution was adopted asking the authorities for regulation of conditions in regard to alien insane. It has been found that many of the interned who required psychiatric treatment and were repatriated at the proper time, have returned to Switzerland, instances being known in which their home authorities paid their transportation back to Switzerland.

Personal.—Dr. Swale Vincent, since 1904 professor of physiology at the University of Manitoba, Winnipeg, has been appointed professor of physiology in the University of London, Middlesex Hospital, and will probably take up his new duties early in May.—Dr. Harold Pringle, lecturer on histology and assistant in physiology in the University of Edinburgh, has been appointed professor of physiology in Trinity College, Dublin, succeeding the late Sir Henry Thompson.

The International Pneumothorax Association.—The *Poli-clinico* announces that now, after the interregnum of the war, the international association entitled *Pneumothorax Artificialis* is to resume its work. The association intends to revive the international review, *Pneumothorax Thérapeutique*, founded by Forlanini, but for the present has made arrangements with *Tuberculosis*, published at Rome, which has agreed to summarize all the works on artificial pneumothorax as they appear in 1920. The secretary of the association is Prof. U. Carpi, Lugano, Italy.

French Children and the World War.—The effect of the war on the children of France is shown in a recent report submitted by the American Red Cross headquarters at Lille, based on the figures of the municipal bureau of hygiene. Before the war the city had a population of 200,000. The birth rate has shrunk from nearly 4,900 in 1913 to only 600 in 1918, and the figures by years indicate a loss of 15,000 births during the war. Since the armistice a survey has been made in all public and private schools to determine the number of children whose development has been retarded, and to place those with signs of tuberculosis in the care of institutions and welfare organizations. Of 18,000 children in the schools of Lille at the time of the armistice, over 6,000 had to be sent to hospitals or convalescent centers, 60 per cent. showed signs of arrested development, while about 40 per cent. gave evidence of glandular or pulmonary tuberculosis. In one typical school, out of 210 examined only one child was in normal health.

Deaths in the Profession Abroad.—Dr. W. Schallmeyer of Munich, whose work, "The Threatened Physical Degeneration of Civilized Races," won the Krupp prize in 1903, aged 62.—Dr. Schottelius, director of the Institute of Hygiene at Freiburg for many years, aged 70, has been missing since last September. He was visiting a lake resort when last seen.—Dr. R. Stierlin, professor of surgery at the University of Munich.—Dr. A. Knoblauch, aged 56, whose atlas of chronic diseases of the nervous system appeared in 1919. He was the constantly reelected president of the Senckenberg Society for Scientific Research at Frankfurt.—Dr. Hoffmann of Heidelberg, author of various works on neurology, aged 62.—The cable brings word of the death of Dr. E. Wertheim, professor of gynecology and obstetrics at the University of Vienna, whose name is associated with operations for uterine cancer.—Dr. Calatraveño, a leading pediatrician, hygienist and medical editor at Madrid and honorary member of numerous scientific societies at home and abroad, aged 58.

LATIN AMERICA

Foot and Mouth Disease in Bolivia.—According to a cablegram received from Bolivia, foot and mouth disease is prevalent among the cattle of the department of Cochabamba.

Plague in Uruguay.—During the recent outbreak of the plague in Uruguay there were seventeen cases with two deaths, all of which occurred at Santa Rosa, department of Canelones, in October and November, 1919.

New Members of the Uruguayan Public Health Council.—Drs. Alfredo Vidal y Fuentes, José Mainginou and José Infanzozzi have been appointed president and members, respectively, of the National Council of Hygiene of Uruguay.

Influenza in Mexico.—A cablegram from Mexico states that the epidemic of influenza continues to spread. In the Military School classes were suspended, and public business is suffering because of the absence of employees. The disease is of a mild type.

New Hospital for Panama.—Construction work on the new national hospital for Panama has been begun at El Hatillo, a high point facing the Pacific in a suburb of Panama. The hospital will cover a site of fourteen acres, and will be composed of eleven reinforced concrete buildings arranged in rectangular form, with accommodations for 600 patients. The construction is in charge of Major Edgar A. Bock, M. C., U. S. Army, at present superintendent of the Santo Tomas Hospital, Panama.

Panama Nurses' Graduation.—At the graduating exercises of the Santo Tomas Hospital Training School for Nurses, January 31, diplomas were presented to the seven graduates by Major Edgar A. Bock, M. C., U. S. Army, superintendent and director of the training school. Thirty-five selected pupils of Panamanian nationality form the school and during its three years of operation twenty-nine diplomas have been awarded to successful graduates, who are now found in several hospitals of South America.

International Sanitary Conference.—The sixth International Sanitary Conference of the American Republics will convene at Montevideo, Uruguay, Dec. 12-20, 1920. The invitations for the conference will soon be sent by the Uruguayan government, and the program will be issued by the International Sanitary Bureau in Washington, of which Dr. Rupert Blue, U. S. Public Health Service, is acting chairman. As indicated by Dr. E. Fernandez Espiro, the chairman of the organization committee, the chief subject for discussion will be the improvement of sanitary conditions in American countries.

Government Services

Health of the Army

For the week ending February 13, influenza continued to be reported from almost all the camps in decreasing numbers. The number of new cases of pneumonia following influenza is also decreasing. The death rate for disease is lower than for the previous week. Among the American forces in Germany, influenza and measles continued about the same, while pneumonia showed a slight increase. Among the American forces in Siberia, influenza and pneumonia were also prevalent.

Eighty-Ninth Division Medical Association

The officers who served with the Eighty-Ninth Division have formed an organization to be known as the Eighty-Ninth Division Medical Association of which Dr. Czar C. Johnson, Lincoln, Neb., is acting organization secretary. The purpose of the organization is to perpetuate the association of the 260 medical officers who at some time served with the division, by keeping a roster of membership and by a reunion at some central place each year for a professional and social meeting. The first reunion will be held in Kansas City, Mo., during the summer or early fall.

Medical Officers Over Fifty May Remain in Service

Senate Bill No. 3668 provides for the retention in service of certain "persons under the age of fifty years," who shall have served as officers of the medical, dental or veterinary corps in the United States Army, the National Guard in the service of the United States or in the National Army between April 6, 1917, and Nov. 11, 1918. It is suggested that, should the Senate do justice to the small number of officers now holding temporary commissions, who will be barred from entering the Medical Corps by reason of having attained the age of fifty years, an amendment be offered to the bill inserting after the words "fifty years" "or complete twenty or more years of commissioned service with regular troops before reaching the age of 64 years," etc. Under the present bill many valuable officers over fifty years of age will be eliminated from the Army.

LONDON

Feb. 7, 1920.

Medical Secrecy in Venereal Cases

Unlike the conditions in other countries, the English law recognizes the inviolability of the medical secret. The question has just arisen in a new form. During the hearing of an undefended suit for divorce brought by the wife, a physician was called on to give evidence that he had treated her for venereal disease. Adultery was proved, but in this country a woman suing for divorce must prove cruelty also. In this case the charge of cruelty was based on the communication of syphilis to her by the husband. A physician from the Westminster Hospital was called to prove that she was suffering from syphilis. Before giving evidence he handed the judge a letter from the chairman of the house committee stating that the hospital had adopted the national scheme for dealing with venereal disease and enclosing a copy of the statutory regulations, one of which enjoined absolute secrecy on the physician who attended the patient. The judge (Justice McCardie) said that the physician was one of those who were desirous of assisting the scheme for treating venereal diseases in every way, and for that purpose he wished loyally to maintain the secrecy which rightly rested on him. But in a court of justice there were even higher considerations than those that prevailed with regard to the professional position of physicians. Apart from the obligation that might be imposed on physicians by the judge, it was desirable that there should be a loyal observance of the confidence that was reposed in them by patients. He then ordered the physician to give evidence, which the latter did, showing the woman was suffering from syphilis. This ruling has not been received without criticism by the profession. Mr. H. W. Bayly, honorary secretary of the Society for the Preven-

tion of Venereal Disease, stated that he felt confident that his committee would agree that physicians should be protected from compulsion to "give away" their patients. There would never be an effective use of the clinics now provided unless the patients had complete confidence that their secrets would not be revealed. If he found himself in the same position, he would refuse to give evidence. This would make him liable to imprisonment for contempt of court but it is doubtful whether any judge would press the matter, as public sympathy would be against him. The *Lancet* also points out the detrimental effect of the ruling on the working of the venereal clinics.

The Influenza Epidemic

The most comprehensive account of the great influenza epidemic has been issued as a government report by Dr. Carnwath. He gives evidence to show that the epidemic originated in China and spread to America and thence to Europe. Glasgow in May, 1918, was the seat of the first outbreak among the civilian population. In June the disease reached England, and the summit of the first wave occurred in the week ending July 13. The early cases were slight, the late ones severe. This was again seen in the autumn wave, the most terrible of all. The ports of Portsmouth, Southampton and Liverpool, which were affected first, suffered lightly. Inland towns suffered later and more severely. The subjoined table gives a comparison of the deaths in London with those in American towns from influenza and pneumonia (all forms) during eight weeks of the epidemic.

DEATHS IN LONDON AND IN AMERICAN CITIES

City	No. of Deaths	Rate 8 Weeks per 100,000 of Population
London	13,744	341
New York	20,631	360
Chicago	8,785	343
Philadelphia	12,806	749
Boston	4,211	548

The number of weeks intervening between the highest points of the summer and autumn epidemics were: London, 15; Liverpool, 14; Manchester, 20; Stockholm, 9; Copenhagen, 12; Chicago, 28. The age incidence showed curious changes. During the summer wave the ages most affected were 15 to 45. In the winter wave there was a considerable shifting toward the extremes of life and particularly toward the younger years. The susceptibility of young children was the subject of a special inquiry in London. Though the attack rate was below the average, the chances of recovery were less than in other age groups. Of breast-fed infants, 30 per cent. contracted the disease; of artificially fed, 54 per cent. The opposite, however, occurred in lying-in homes. An inquiry in Cheshire revealed that 25.4 per cent. of expectant mothers affected died, and of 118 expectant lives only fifty-seven survived. It does not appear that one attack was invariably powerful in protecting against others. The results are contradictory, but may be reconciled by the hypothesis that there are several strains of the influenza virus, and that these vary in virulence and antigenic potency. On this explanation, infection with one strain confers little or no protection against infection with others. Each wave seemed to have its peculiar dominant strain producing a certain wave individually.

The Fellowship of Medicine

At a meeting of the executive committee of the Fellowship of Medicine and Post-Graduate Association, at which Sir Humphrey Rolleston presided, a resolution was passed in silence recording the profound sorrow of the association at the loss of their president, Sir William Osler, without whose guidance and support success would have been impossible. A plan for the establishment of postgraduate courses was submitted by a special subcommittee and approved. Three series of courses are contemplated: 1. Postgraduate courses for general practitioners. A series of courses dealing with the various clinical subjects from the general practitioner's point of view, each lasting a fortnight or more, should be arranged by single institutions or by groups of institutions. These institutions would be of two kinds: (a) those, such as the existing postgraduate institutions, providing postgraduate instruction through the greater part of the year, and (b) those undergraduate schools which are willing to provide short courses from time to time. 2. Postgraduate advanced and special courses. Consecutive series of advanced courses, each series dealing with one clinical subject from the spe-

cialist or advanced point of view, should be arranged by educational subcommittees to be elected annually by separate meetings of London teachers, including the councils of the corresponding sections of the Royal Society of Medicine. 3. Postgraduate students preparing for special examinations. Courses for special examinations should be arranged by individual schools, as has been done in the past.

Increase of Women Physicians

The great increase in the number of women physicians in this country since the war began has been pointed out in previous letters to *THE JOURNAL*. It is now foreseen that by 1925 there will be a very large number, for nearly 3,000 woman students are taking up medicine today. The Women's School of Medicine is quite full. There are many reasons for this. First, there was a scarcity of men physicians brought about by the war. Then, a large number of openings arose, owing to the progressive public attitude toward social welfare and child life. These appointments will increase from year to year as it is realized what great factors the clinic and the medical inspector are in the educational and industrial worlds. The girls who are training to become physicians are mostly from the middle professional class, some are the daughters of rich merchants, who are determined to be independent, and others are from the families of the once leisured class, now described as the "new poor" (people made poor by the rise in the cost of living with no counter-balance).

Criticism of the Insurance Act

Dr. Addison, minister of health, received a deputation from the British Federation of Medical and Allied Societies with regard to the national insurance act. Dr. Arthur Latham said that the deputation came to emphasize the fact that national health insurance did not permit the insured persons to receive all that the science of medicine had to give, and under the regulations the physician was not able to do the effective work he was willing and anxious to do. They had the lessons of five years' experience during the war of the most gigantic experiment in health services the world ever saw. The insured public asked for bread and were given a stone. They asked for health and were given regulations which seemed to be chiefly designed to catch the erring physician in some fault. The tendency of the regulations was to impair the efficiency of the health services. At the end of the war the medical arrangements were far more effective than at the beginning, and under the compelling force of great events, modern methods were able to push their way through regulations. There must be regulations; but if they were not to hamper efficiency, they must be elastic. None of the lessons of the war had been incorporated in the regulations of the insurance act. The deputation suggested a public inquiry into the working of the act.

Dr. Addison said he was grateful for the efforts of the federation to focus trained medical opinion on the question how the medical services of the country could best serve the public. He invited its help in devising a scheme whereby a strongly individualistic profession, such as the medical, could be brought with good will to devote its services commonly to the public necessity. The type of service he was aiming at had been remitted to the consultative council, and as soon as he received the report it would be made public. Should a wider inquiry be found necessary it could be undertaken.

The St. Andrews Institute for Clinical Research

On retiring from practice in London, Sir James Mackenzie took up his residence in the small Scotch town of St. Andrews, where he has founded an institute for clinical research of a new type to carry out methods of investigation which he has long advocated. He considers that the methods of physiology and bacteriology which have helped some sections of medicine are not applicable by themselves to the wider fields of clinical medicine. What is necessary is a much more profound and systematic study of symptoms than has been accomplished in the past. Disease is made manifest only by symptoms. Therefore, the first step is to understand the nature and significance of symptoms. The structural stage of disease when it has caused structural damage has been fairly well studied, but not so the early stages before the occurrence of physical signs, and the causes which predispose to disease. St. Andrews has a population of only 10,000, but this is considered an advantage, as the inhabitants are less migratory than in larger towns and it is therefore easier to keep in touch with them. The

object is to study not the rarer forms of disease but the most common. Arrangements have been made with the physicians on the insurance panel by which their patients will attend the institute at regular hours. Each physician will have at his disposal a separate room and all the facilities of the institute. A chemist has been appointed on the staff, and it is intended to appoint a bacteriologist. The professors of anatomy and physiology of St. Andrews University will give help and also—a peculiar innovation—the assistant professor of logic.

Ventilation of Places of Amusement

The Public Health Committee of the London County Council is recommending the enforcement of regulations for the more effectual ventilation of places of amusement, and the exclusion of children, as precautionary measures against the spread of infectious diseases. The theaters and music halls committee of the council has already expressed the opinion that the only efficient means of securing satisfactory atmospheric conditions in a place of entertainment and thereby preventing as far as possible the spread of infection is the installation of an adequate system of mechanical ventilation combined with a system of heating under which fresh air is warmed before it enters the building. Experience has shown that unless incoming air is warmed, the mechanical ventilation system is not fully utilized, owing to the cold draft caused. Such a combined system is required in all new places of entertainment and, as opportunity offers, in existing places. A similar policy has been pursued with regard to the provision of means of natural lighting, so that daylight may be freely admitted into halls when not in use for cinematograph displays.

PARIS

Jan. 22, 1920.

A Confederation of French Scientific Societies

In my letter of January 15 (*THE JOURNAL*, Feb. 21, 1920, p. 538) I mentioned the circumstances that had led certain societies to form federations. The chemical societies were the first to take such action. Soon afterward the societies of natural science followed their example, and now a federation of the societies of physical science is about to be organized. On the initiative of M. Moureu, professor in the *Ecole supérieure de pharmacie de Paris*, and member of the Academy of Medicine and the Academy of Science, a meeting of the representatives of these various federations has been called to discuss the feasibility of forming a general confederation of federated scientific societies. About forty scientific societies were represented at this meeting, and it was unanimously decided to form such an organization. The purpose of this confederation will be to establish intimate relations between the groups of the different branches of pure and applied science; to coordinate their efforts from a scientific, technical and economic standpoint, and to further the development of all movements destined to contribute to the progress of pure and applied science, with a view to promoting the economic welfare of the country, and to increasing the general prosperity.

Difficulties That Scientific Publications Are Facing

Everything pertaining to printing and publishing is associated with difficulties nowadays. First, there is the shortage of paper to contend with; then there is the scarcity of labor, the lack of suitable buildings, transportation difficulties, the deficiency of coal, etc. This state of affairs not only retards the publication of scientific journals, but threatens their very existence. Some publications whose fine general appearance justifies a considerable increase in price or whose subscription list is growing rapidly can endure all these inconveniences, but with scientific publications it is different, for their patronage is necessarily limited. This condition of things is beginning to attract considerable attention in scientific circles, and, quite recently, M. Henneguy, professor in the *Collège de France*, took the initiative and called a meeting of the managing directors and secretaries of the scientific publications, and representatives of the federations of societies of learning. Ways and means of remedying the unfavorable conditions were discussed. A proposal to establish a cooperative society to handle the printing and publishing of scientific journals was considered, reference being made to the university press idea as carried out in England and America (*Oxford University Press*, and many others), but it was thought to be impossible or impracticable to adopt the university press plan in toto, although it was admitted that certain commercial

features on which it is based may well be imitated. Any cooperative plan would have to be based, above all, on a complete inventory of French scientific publications, and would necessitate as wide a curtailment as possible. This implies, of course, the necessity of raising considerable funds; state aid would have to be secured; private contributions would need to be solicited, and an issue of stock would have to be made. In short, as a cooperative society could not be established over night, it was thought best to face the immediate needs of the scientific publications.

After this exchange of opinions, in which many men well known in the scientific world took part, M. Henneguy moved that a committee be appointed to study into the matter. His motion was unanimously adopted. Accordingly, the *Comité d'étude de la presse scientifique* was chosen to investigate the question and to report on these three matters pertaining thereto: 1. What plan can be adopted to print and publish works needed for scientific documentation, journals of pure and applied science, and works on pure science, so that they can be sold at a reasonable price, authors and writers be paid a just remuneration, and a maximal output be secured? 2. What journals already in existence or about to be founded could be so associated as to make possible eventually the plan of a cooperative printing and publishing house? 3. How may, eventually, French scientific publications be grouped and classified so as to avoid duplication of effort, and favor, on the other hand, the founding of new journals, if such should seem needed?

Medical Science and Aeronautics

The sixth Salon de l'Aéronautique, recently held in Paris, gave abundant evidence of the progress that medical science as applied to aerial navigation has made during the past six years, since the last Salon de l'Aéronautique was held in 1913. The physiologic section of military aviation was especially interesting. It covered six display booths. The first booth comprised everything that pertains to the general examination of the would-be aviator, including means of identification, height, weight, musculature, bones and joints. The second and third booths were devoted especially to the nervous system and the organs of sense: study of the functions involved in walking, the coordination of movements, the equilibration apparatus, and the examination of vision and audition. In the fourth booth, examinations of the circulation, blood pressure, and respiration were conducted. The fifth and sixth booths took up roentgenoscopy and the laboratory examination. The general impression that one gained at this exhibit was that medical science has made exceedingly important contributions to the progress of aeronautics, not only as regards the establishment of the standard which a candidate for the post of pilot must attain to in the medical examination, but also with respect to the limitation of the dangers of aviation in general. From the prophylactic point of view, the automatic oxygen inhaler may be mentioned particularly. The Garsaux inhaler is so constructed that oxygen to the extent of 35 liters an hour for each passenger is supplied automatically as soon as an altitude of 3,500 meters is reached. The amount of oxygen furnished increases gradually, until, at an altitude of 8,000 meters, 150 liters an hour are supplied.

Marriages

HENRY BLODGETT MCINTYRE, Lieut.-Col., M. C., U. S. Army, on duty at Fort McHenry, Md., to Miss Gladys E. Miller, at Mamaroneck, N. Y., January 31.

GEORGE LYLE VENABLE, New Sharon, Iowa, to Miss Georgia Jinks of North Manchester, Ind., in the chapel of St. Luke's Hospital, Chicago, February 3.

MATTHIAS HIGGINS, JR., Newport, Ky., to Mdle. Germaine Perillion of St. Etienne, France, in New York City, February 7.

WILLIAM H. MATCHETTE to Miss Nellie Turner, both of Greenville, Ohio, at Covington, Ky., Dec. 22, 1919.

ARTHUR LAWRENCE NIELSON, Kansas City, Mo., to Miss Katherine Krug of Washington, D. C., January 24.

RALPH HENRY DUNNING, Syracuse, N. Y., to Miss Georgia Malone of Lancaster, Ohio, January 27.

THOMAS CONROY ELEY, Plymouth, Ind., to Miss Gertrude Spiegel of Indianapolis, February 18.

Deaths

John Walton Ross * Pasadena, Calif.; Tulane University, New Orleans, 1868; aged 77; medical director (captain), U. S. Navy, retired; who entered the Navy in 1870, and was retired Jan. 11, 1905, on attaining the age of 62 years, after ten years and one month of sea service; and who since his retirement had resided in California; an expert in yellow fever; chief of the department of charities and hospitals in Havana during the American occupation of Cuba, and director of the hospitals of the Canal Zone; a member of the Association of Military Surgeons of the United States; died, February 9.

Joseph Ashton Blanchard, Shreveport, La.; College of Physicians and Surgeons, Baltimore, 1897; aged 45; formerly city physician of Shreveport; a member of the Louisiana State Medical Association; captain and assistant surgeon, First Regiment, Louisiana Volunteers, during the war with Spain; was found dead in his room in a hotel in Memphis, February 4, from a gunshot wound of the head, believed to have been self-inflicted, with suicidal intent.

Joseph Nelson Clark, Harrisburg, Pa.; Georgetown University, Washington, D. C., 1867; aged 80; for many years a druggist of Harrisburg; a veteran of the Civil War; president of the People's Savings Bank of Harrisburg; a school director for eleven years, and for one year secretary of the board; died, February 5, from bronchopneumonia.

James Jackson Johnson, Braggs, Okla.; University of Louisville, Ky., 1907; aged 35; sergeant first class, Medical Department, U. S. Army, for six years, and later attached to the American Red Cross Commission to Siberia; died, Dec. 13, 1919, from typhus fever, and was buried with military honors at Irkutsk, Dec. 16, 1919.

Harry John Tate, Pittsfield, Mass.; Georgetown University, Washington, D. C., 1914; aged 30; first lieutenant, M. C., U. S. Army, with service abroad; a member of the Massachusetts Medical Society; city physician of Pittsfield; died in the House of Mercy Hospital, Pittsfield, February 11, from pneumonia.

Hiram M. Day, Delaware, Ohio; Western Reserve University, Cleveland, 1881; aged 65; a member of the Ohio State Medical Association, and once president of the Delaware County Medical Society; formerly president of the Farmer's Bank, Pandora, Ohio; died, February 2, from heart disease.

George Henry Balleray * Paterson, N. J.; College of Physicians and Surgeons in the City of New York, 1869; aged 71; a fellow of the New York Academy of Medicine, and of the British Gynecological Society; for ten years surgeon to the Woman's Hospital, Newark; died, February 11.

John Stevenson Tinker * Philadelphia; University of Pennsylvania, Philadelphia, 1908; aged 45; a member of the eye, ear, nose and throat staff of the Polyclinic Hospital and Bethany Dispensary, Philadelphia; died, February 8, in the Polyclinic Hospital, from pneumonia.

William Leckie Bain, Chicago; College of Physicians and Surgeons in the City of New York, 1884; aged 60; for several years a resident of Denver; a specialist in the electrolytic treatment of copper ores; died, January 30, from locomotor ataxia.

Michael Charles Dunnigan, Erie, Pa.; University of the City of New York, 1868; aged 80; formerly town clerk and treasurer of Erie; president of the Erie Board of Health in 1899; died, February 5, from cerebral hemorrhage.

Otto A. Hartwig, St. Louis; Missouri Medical College, St. Louis, 1880; aged 76; a member of the Missouri State Medical Association; for more than twenty-five years a pharmacist; died, February 3, from bronchitis.

James E. Cole, Hazelwood, N. C., formerly of Middleton, Ga.; Southern Medical College, Atlanta, Ga., 1890; aged 54; a member of the Elbert County Board of Education; died, February 3, from cerebral hemorrhage.

Alexander Samuel Harshberger * Lewistown, Pa.; University of Pennsylvania, Philadelphia, 1870; aged 70; local surgeon for the Pennsylvania Railroad for thirty-two years; died, February 11, from pneumonia.

Joseph Patrick Deery, Fairfield, Conn.; Maryland Medical College, Baltimore, 1913; Kansas City (Mo.) College of Medicine and Surgery, 1917; aged 34; died at Bridgeport, Conn., February 2, from pneumonia.

Harvey Sturgeon Foringer, Wilkesburg, Pa.; College of Physicians and Surgeons, Baltimore, 1896; aged 60; for the last fifteen years a representative of a pharmaceutical house; died, February 4, from pneumonia.

Howard L. McKinstry, Red Wing, Minn.; University of Pennsylvania, Philadelphia, 1870; aged 71; died at the home of his daughter in Granite Falls, Minn., February 7, from cerebral hemorrhage.

Edwin Howe, Los Angeles; Physio-Medical College, Cincinnati, 1851; aged 91; for more than sixty years a practitioner of St. Joseph, Mo.; died, Dec. 29, 1919, from cardio-renal disease.

William Thomas Vance, Bloomsburg, Pa.; University of Maryland, Baltimore, 1881; aged 68; a member of the Medical Society of the State of Pennsylvania; died, January 30, from heart disease.

John F. Taggart, New Washington, Ind.; Jefferson Medical College, 1860; aged 83; surgeon of the Fourth Indiana Volunteer Cavalry during the Civil War; died, Nov. 30, 1919, from epithelioma.

John Thomas Phillips, Newport, Wash.; Rush Medical College, 1897; aged 49; president of the Security State Bank of Newport; once mayor of Newport; died, February 11, from influenza.

Malcolm Munroe Campbell, Albany, Mo.; University of Michigan, Ann Arbor, 1871; Bellevue Hospital Medical College, 1875; aged 80; died in a hospital in St. Joseph, Mo., February 10.

William Frank Kistler, Minersville, Pa.; Hahnemann Medical College, Philadelphia, 1874; aged 68; died at his winter home in St. Petersburg, Fla., January 30, from cerebral hemorrhage.

Oscar Loehr, Milwaukee; University of Berlin, Germany, 1880; aged 65; died in Alexian Brothers Hospital, Chicago, February 9, from uremia following an operation for prostatic abscess.

Edward August Arnold, East Orange, N. J.; Cornell University, New York City, 1909; aged 32; house physician at the Orange Memorial Hospital; died, February 5, from pneumonia.

John Jasper Sewall, Newport, Me.; University of the City of New York, 1887; aged 62; a member of the Maine Medical Association; died, February 3, after a surgical operation.

George Philip Bentel, Louisville, Ky.; University of Louisville, Ky., 1880; aged 72; died in St. Anthony's Hospital, Louisville, February 7, from shock after a surgical operation.

Walter DeWolf Jones, Dierks, Ark.; Philadelphia University of Medicine and Surgery, 1867; aged 75; a veteran of the Civil War; city health officer of Dierks; died, February 4.

Daniel Henry Arendale, Mount Vernon, Ill.; University of Nashville, Tenn., 1884; aged 62; died at his farm, near Mount Vernon, January 30, from acute dilatation of the heart.

Henry Rudolph Widmer * Newark, N. J.; College of Physicians and Surgeons in the City of New York, 1903; aged 38; died, February 1, from cerebral hemorrhage.

Joseph LeRoy Gross, Pittsburgh; Jefferson Medical College, 1919; a member of the house staff of Mercy Hospital, Pittsburgh; died, February 5, from pneumonia.

Clarence Homer Kemp, Elmwood, Ill.; Rush Medical College, 1896; aged 49; a member of the Illinois State Medical Society; died, January 30, from pneumonia.

Arthur G. Thome, Chicago; Chicago Homeopathic Medical College, 1883; aged 62; died in the Chicago Union Hospital, February 17, from heart disease.

William P. Van Sant, Brooklyn, Ind.; Columbus (Ohio) Medical College, 1880; aged 68; died in the Methodist Hospital, Indianapolis, Dec. 5, 1919.

George Washington Hart, Brooklyn; College of Physicians and Surgeons in the City of New York, 1901; aged 46; died, February 7, from pneumonia.

Caryl B. Storrs, Minneapolis; Michigan College of Medicine and Surgery, Detroit, 1892; aged 49; died, January 18, as the result of an accident.

George W. W. Walker, Roseville, Ohio; Zanesville (Ohio) Academy of Medicine, 1875; aged 73; died, February 6.

Correction.—Dr. James Jefferson Johnson, whose death was announced in THE JOURNAL of February 14, states that there must be an error in name as he is still alive and practicing at Sulphur Springs, Texas. The physician who died was Dr. James Jackson Johnson.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

ANTIPLASMA

J. J. Rudolph's Alleged Specific for Malaria

During the last few months THE JOURNAL has received a large number of inquiries from the South relative to a nostrum that is being sold in that part of the country under the name "Antiplasma" or "Rudolph's Malarial Specific." According to the advertising, the preparation was "developed by J. J. Rudolph, M.D." who, we are told is "one of the leading physicians in America." This, while an obvious enough joke to the medical profession, may be taken seriously by the general public and thus contribute duly to the sale of "Antiplasma." The story goes that Dr. Rudolph during the Boer War collaborated with "Dr. Kruger, the Chief Medical Officer of the Boer Army" and that, between them, they

Chloroform from which the same is obtained, in reducing fever. But neither Quinine or Arsenic are in reality Specifics. They do not cure; they effect temporary relief. In cases of malaria, Quinine may be taken.

Avoid Mosquitos!! There is only one way to cure Malarial Fever. Take 15 drops of Rudolph's Malarial Specific on sugar, or in molasses, three times daily for six days!!

A remarkable remedy has just recently come to light, which will revolutionize the methods of treating this disease. During the time of the Boer War, Dr. Rudolph, one of the leading physicians in America, had occasion to collaborate with Dr. Kruger, the Chief Medical Officer of the Boer Army. These Doctors developed a specific for malaria, with the result that not a single death occurred among the Boers as a result of malarial infection.

Reproductions (reduced) from the circular which is wrapped around the bottle of "Antiplasma."

"developed a specific for malaria with the result that not a single death occurred among the Boers as a result of malarial infection."

In orthodox "patent medicine" style it is declared that quinin—universally recognized as one of the few specifics in medicine—is not in reality a specific at all:

"There is only one way to cure Malarial Fever. Take 15 drops of Rudolph's Malarial Specific on sugar or in molasses, three times daily for six days."

"In no instance has a case not yielded to treatment and a complete and lasting cure effected within seven days."

This marvel, it seems, after the close of the Boer War lay dormant for years and "has just recently come to light"; it "will revolutionize the methods of treating this disease." We are told that for eighteen years past "Dr. Rudolph has used this compound in his private practice in America and has proved its efficacy beyond question and to the complete satisfaction of a number of reputable scientists." Search of medical literature, however, fails to show that Dr. Rudolph has given the world, medical or otherwise, any information regarding his epoch making discovery. Apparently, this "leading physician" kept to himself the knowledge of his "specific" for one of the most widespread diseases known, until he decided that the time had come to commercialize it.

A number of original, sealed packages of Antiplasma were

turned over by THE JOURNAL'S Propaganda department to the A. M. A. Chemical Laboratory. Here is the chemist's report on the product:

"'Antiplasma' ('Rudolph's Malarial Specific') is a pale yellow, viscid liquid having an odor resembling a mixture of oil of turpentine and oil of wintergreen. Its taste is aromatic and bitter, somewhat like the resinous exudates from spruce. On heating, the substance burned with a smoky flame, leaving only a trace of ash. The specific gravity was found to be 0.97924 at 25 C. On distillation with steam, Antiplasma gave a volatile fraction and a non-volatile portion, the latter amounting to 52.9 per cent. of the weight taken. The non-volatile residue was a pale yellow solid which softened to a thick, viscous fluid at 100 C. The odor of the warmed substance was pine-like. It responded to the usual tests for rosin. The distillate appeared to be a mixture of oil of turpentine and methyl salicylate (oil of wintergreen). Quinin and arsenic, two remedies frequently used in the treatment of malaria, were absent. It was impossible to determine by the analysis whether the product had been made by warming a mixture of rosin, oil of turpentine and methyl salicylate or by 'thinning' some natural turpentine-like product with methyl salicylate.

"A mixture of 53 parts of bleached rosin, 41 parts of oil of turpentine and 6 parts of methyl salicylate would probably have whatever anti-malarial properties Antiplasma possesses."

Correspondence

STATUS OF ARSPHENAMIN PATENTS

To the Editor:—In response to requests from a number of physicians concerning the status of the arspenamin patents, I submit data on the subject in the hope that they will interest the readers of THE JOURNAL.

During the recent war, Congress passed a law, known as the "Trading with the Enemy Act," which, among other things, conferred on the President the authority to license American citizens to operate enemy-owned patents. This power was by executive order delegated to the Federal Trade Commission, which granted, after due consideration, licenses to certain applicants. Licensees under this law were to pay 5 per cent. of their gross receipts to the alien property custodian, who was to deposit the same in the United States Treasury. Within a year after the declaration of peace, the foreign owners of the patents were given the right to sue in a court of equity for the payment of a reasonable royalty (presumably the said 5 per cent.) and also to petition the court for a termination of the license granted.

These provisions of the Trading with the Enemy Act have been to a large extent nullified by certain clauses in the treaty of peace, bearing on seized property. An amendment to the Trading with the Enemy Act permitted the alien property custodian to regard patents as property and to seize and sell such property as was owned by enemy aliens. The alien property custodian thereupon seized the 4,500 German chemical patents in the United States, including those covering drugs, dyestuffs and the like. These were sold to the Chemical Foundation for \$250,000.

The purposes of this corporation have been misunderstood in certain quarters. The Chemical Foundation is to be conducted *pro bono publico* and its by-laws exclude the possibility of private gain. Its object is to protect the struggling dye industries of this country and to stimulate and aid scientific research in industrial and medical chemistry; the profits accruing from the royalties paid to it on patents are, after redemption of the preferred stock, to be utilized in grants for these purposes. Its trustees are prominent men of known public spirit and of unimpeachable honor.

The title of the Chemical Foundation to the patents appears to be absolute and irrevocable. Congress specifically limited any claim on the part of the former foreign owners to the proceeds of the sale and not to a recovery of the patents. The peace treaty, in Article 297, validates and confirms the acts of the alien property custodian, and Germany

thus acquiesces in the loss of these patents. The treaty further provides that the German owners of seized patents cannot seek financial redress from the American licensees, but shall look to the German government, which shall indemnify her citizens to the extent of the claims due. The German owner of patents granted before the war is no longer entitled to manufacture in the United States, or to import his products into the United States.

The arsphenamin patents now being the property of the Chemical Foundation, the German manufacturer cannot export the drug to this country without infringing the patent ownership. The laboratories in the United States now manufacturing arsphenamin will enjoy this privilege for the duration of the patent, which on this particular drug extends to 1928. Royalties must, of course, be paid by them to the Chemical Foundation, which may, in its judgment, license additional laboratories to produce this compound and other similar compounds. As to new patents in the future, Germany will be protected as she was in the days before the war. The licensing of persons to furnish arsphenamin and neo-arsphenamin throughout the United States was in the beginning carried out by the Federal Trade Commission under regulations formulated by the United States Public Health Laboratories. It may be safely asserted that in no country in the world is the distribution of these products so thoroughly controlled and regulated as in the United States. Compounds must contain a definite percentage of arsenic within narrow limitations, and must pass rigorous toxicity tests in animals. In Germany the original product was tested by subcutaneous injections in mice. The laboratories referred to above have wisely substituted intravenous injections in rats.

Great credit is due to Dr. G. W. McCoy, director of the United States Public Health Laboratories, for the manner in which he has organized the scientific supervision over the arsenical products, and to Prof. Julius Stieglitz of the University of Chicago, who has acted as the government's expert on arsphenamin throughout the entire period of the war, and who has made many personal sacrifices in the interests of the country.

JAY FRANK SCHAMBERG, M.D., Philadelphia.

AMERICANIZATION OF THE MEDICAL PROFESSION

To the Editor:—Would not this be a propitious time for the various states to enact laws requiring full citizenship of all physicians, etc., who may hereafter apply for a license to practice? Educational institutions should be open to all, irrespective of nationality or citizenship, but medical societies, clubs, and similar organizations might aid considerably in the work of Americanization were they to require citizenship as an essential qualification for membership. Honorary memberships could be extended to nonresident foreigners of eminence.

WILLIAM H. HOLMES, M.D., Chicago.

"A MODIFIED TECHNIC IN OPERATION FOR OBLIQUE INGUINAL HERNIA"

To the Editor:—I have read, with no little interest, Dr. Angwin's article (*THE JOURNAL*, Feb. 14, 1920, p. 437) on the subject of a modified technic in the operation for oblique inguinal hernia. Having served at the Naval Hospital at Great Lakes during Dr. Angwin's duty there, I had a chance to observe some of his methods of both herniotomy and varicocele operations, both of which vary somewhat from the classical. One of the main advantages in his technic in herniotomy, which is not emphasized in the article, is the lessening of traumatism to the cord structures. This small factor not only relieves the patient of postoperative distress, but also lessens the dangers to the veins and vas in the cord.

On the other hand, the principle of anchoring the peritoneum to a structure outside the abdomen, however strong, does not appear desirable. Intra-abdominal structures resemble the caged lion, continually moving about seeking a weak place in the cage. To anchor the peritoneum, at or

very near the point of a previous hernia, necessarily leaves a predisposing point for subsequent trouble. Closure of the clean peritoneum will, I think, give the best results when not securely anchored, but allowed to heal as it is normally found, free, movable and smooth.

B. V. McCLANAHAN, M.D., Galesburg, Ill.

"COMMERCIAL DOMINATION OF BIOLOGIC THERAPEUTICS"

To the Editor:—I wish to express appreciation of your editorial on the "Effects of Quinin on the Tissues," in *THE JOURNAL*, February 14, and to congratulate you on the splendid article on "Commercial Domination of Biologic Therapeutics," in Current Comment in the same issue. The latter subject is a suitable one for an editorial, in which you should place the matter even stronger than you did in this article. In fact, I think this subject is one that justifies repeated editorials from time to time.

C. C. BASS, M.D., New Orleans.

RESPIRATORY SOUNDS HEARD ON THE HEAD

To the Editor:—Apropos of the letter of Dr. Myerson in *THE JOURNAL*, Feb. 14, 1920, regarding respiratory sounds heard on the head, I should like to call attention to the difference in degree of sound transmission between a healthy and a diseased mastoid. Both the respiratory sounds and sound such as that produced by tapping on the central incisors are transmitted better to a bell stethoscope on the diseased side. In mastoiditis this fact becomes of diagnostic importance.

ARTHUR C. JACOBSON, M.D., Brooklyn.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

PHYSICIANS AND THE PROHIBITION LAW

To the Editor:—Please advise me whether or not it will be necessary for me to execute a bond for \$1,000 to the federal government in order to get a permit to purchase 6 quarts of whisky to be used in emergency cases that may occur in my regular practice during any one year, the whisky to be furnished with no charge whatsoever. I have been told that the bond is necessary, but I do not so understand from the article on "The Physician and the Prohibition Law" (*THE JOURNAL*, Jan. 31, 1920, p. 342).

G. P. ZIRKLE, M.D., Kingston, Tenn.

ANSWER.—Treasury Decision 2940, issued Nov. 6, 1919, provided that all persons holding permits to purchase whisky or alcohol must give bond to the minimum amount of \$1,000. Internal Revenue Regulations 60, issued late in January, 1920, superseded previous regulations and modified this rule by providing, as stated in the article mentioned, that unless otherwise required by the commissioner, bonds need not be filed by physicians, dentists or veterinarians. This means that except in special cases in which the commissioner may see fit to require a bond, physicians do not need to file a bond to secure a permit.

VACCINATION WITHOUT SCAR

To the Editor:—Please describe the technic of vaccination without scar, referred to in *THE JOURNAL*, Jan. 24, 1920. What is the best variety of vaccine to use, how is it diluted, what is the size of the dose, is it given endermically or hypodermically, and how far should the needle be introduced? In children should the site of injection be anesthetized with a toothpick dipped in pure phenol?

HENRY F. HOYT, M.D., Long Beach, Calif.

ANSWER.—The subcutaneous method of vaccination was described by J. R. Goodall (*Am. J. M. Sc.* 158:721 [Nov.] 1919), who employs the following technic: Vaccine put up in capillary tubes is used. These are put in denatured alcohol for a few minutes, then dried with aseptic absorbent cotton,

the ends broken off, and the vaccine blown into a beaker by means of a sterile rubber bulb fixed to the end of the tube. From one half to three quarters of a tube of vaccine is allowed for each person, and sufficient sterile water is added to make the individual injection 1 c.c. The arm is sterilized with iodine and the vaccine injected with a fine hypodermic needle and syringe diagonally into the subcutaneous tissues. In a few cases in which the injection was made intradermically, the typical reactions of ordinary vaccination developed without complications. In the others the local reaction was much like that after antityphoid inoculation and usually set in between the second and fourth days, but in a few cases was considerably delayed even for from twelve to fifteen days. Everything should be done with surgical cleanliness, and the needle should be changed for each injection. Children undergo hypodermic vaccination without any difficulty by this comparatively painless procedure. If only one or two persons are to be vaccinated, the vaccine may be prepared as for ordinary hypodermic injection. It should be understood that the method is not yet generally accepted.

"PROCAIN"—BOOKS ON GONORRHEA—SYPHILIS—MALARIA

To the Editor:—1. What is the difference between novocain and procain?

2. Which is the least toxic?
3. What percentage of each should be used on all parts of the body with the exception of the gums?
4. What percentage is safe for extraction of teeth?
5. What is the maximum amount in grains or fractions that is safe for use in one operation?
6. Please refer me to a good book on (a) the treatment of syphilis of all types; (b) the treatment of gonorrhea and its sequelae; (c) malaria and its treatment.

I note what THE JOURNAL has to say about apothesine. I am glad that there is such a publication to speak out boldly against all pretenses.

W. B. PALMER, M.D., Furman, Ala.

ANSWER.—1. None. The term "procain" was adopted by the Federal Trade Commission and the Council on Pharmacy and Chemistry for use in place of novocain, which is the trade name for this product used by a single firm. "Procaine" is the term used by the American firms which have been licensed by the Federal Trade Commission to manufacture the drug.

2. See Answer 1.

3. According to New and Nonofficial Remedies, for infiltration anesthesia, solutions of 0.25 gm (4 grains) of procain in 100 or 50 c.c. (3.2 or 1.6 ounces) of physiologic sodium chlorid solution, with 0.3 or 0.6 c.c. (5 or 10 minims) of epinephrin solution (1:1,000); for instillations and injections, solutions of 0.1 gm. (1½ grains) procain in 10 or 5 c.c. (16 or 8 minims) physiologic sodium chlorid solution (1:1,000); in ophthalmology, 1 to 5 to 10 per cent. solution; in rhinolaryngology, 5 to 20 per cent. solutions are recommended, with the addition of 0.4 to 0.5 c.c. (6 to 8 minims) of epinephrin solution (1:1,000) to each cubic centimeter (16 minims).

4. See Answer 3.

5. Internally, owing to its feeble toxicity, it may be given in doses up to 8 grains. It might therefore be said that this is the maximum amount to be used in any operation.

Washington July Examination

Dr. C. N. Suttner, secretary of the Washington Board of Medical Examiners, reports the written examination held at Seattle, July 1-4, 1919. The examination covered 13 subjects and included 143 questions. An average of 60 per cent. in each subject was required to pass. Of the 35 candidates who took the physician's and surgeon's examination, 34, including 2 osteopaths, passed, and 1 failed. The following colleges were represented:

College	PASSED	Year Grad.	Number Licensed
College of Medical Evangelists	(1917)	1
George Washington University	(1912)	1
Bennett College of Eclectic Medicine and Surgery	(1897)	1
College of Phys. and Surgs., Chicago	(1903), (1910)	2

Sufficiency of Evidence of Typhoid Fever from Drinking Contaminated Water

(*Stubbs v. City of Rochester (N. Y.), 124 N. E. R. 137*)

The Court of Appeals of New York says that this action was brought by the plaintiff to recover damages alleged to have been sustained by him as the result of drinking contaminated water from the defendant's domestic service, in 1910. The trial resulted in a judgment for the defendant, which was affirmed by the appellate division of the supreme court, but that is here reversed, and a new trial granted, by this court, divided four to three. The important question in the case was, Did the plaintiff produce evidence from which inference might reasonably be drawn that the cause of illness was due to the use of contaminated water furnished by the defendant? Counsel for the defendant argued that, even assuming that the city might be held liable to the plaintiff for damages caused by its negligence in furnishing contaminated water for drinking purposes: (a) The evidence adduced by the plaintiff failed to disclose that he contracted typhoid fever by drinking contaminated water; (b) it was incumbent on him to establish that his illness was not due to any other cause to which typhoid fever might be attributed for which the defendant was not liable. Counsel asserted that there was a failure of proof on the part of the plaintiff, in that he did not establish that he contracted disease by drinking contaminated water, and in support of his argument cited a rule of law that when there are several possible causes of injury for one or more of which a defendant is not responsible, the plaintiff cannot recover without proving that the injury was sustained wholly or in part by a cause for which the defendant was responsible. If the argument should prevail, and the rule of law stated is not subject to any limitation, this case would illustrate the impossibility of a recovery in any case based on like facts.

One cause of typhoid fever was stated to be "personal contact with typhoid carriers or other persons suffering with the disease, whereby bacilli are received and accidentally transferred by the hands or some other portion of the person or clothes to the mouth." Concededly, a person is affected with typhoid some weeks before the disease develops. The plaintiff here resided three miles from his place of employment, and traveled to and from his work on the street car. To prove the time when he was attacked with typhoid, then find every individual who traveled on the same car with him, and establish by each one of them that he or she was free from the disease even to his or her clothing would be impossible. Again, the evidence disclosed that typhoid fever is caused by sources unknown to medical science. If the word of the rule stated were to prevail, the plaintiff would be required to eliminate sources which have not yet been determined or ascertained. This court does not believe the rule stated to be as inflexible as claimed for it. If two or more possible causes exist, for only one of which a defendant may be liable, and a party injured establishes facts from which it can be said with reasonable certainty that the direct cause of the injury was the one for which the defendant was liable, the party has complied with the spirit of the rule.

The plaintiff was employed in the immediate locality where the water was contaminated. He drank the water daily. The consumption of contaminated water is a very frequent cause of typhoid fever. In the locality there were a large number of cases of typhoid fever, and near to sixty persons who drank the water and had suffered from typhoid fever in that neighborhood appeared as witnesses on behalf of the plaintiff. The plaintiff gave evidence of his habits, his home surroundings, and his method of living, and the medical testimony indicated that his illness was caused by drinking contaminated water. Without reiteration of the facts disclosed on the trial, the court does not believe that the case on the part of the plaintiff was so lacking in proof as matter of law that his complaint should be dismissed. On the contrary, the most favorable inferences deducible from the evidence for the plaintiff were such as would justify a submission of the facts to a jury as to the reasonable inferences to be drawn therefrom, and a verdict rendered thereon for either party would rest, not in conjecture, but on reasonable possibilities

Unconstitutional Exemption Law Relative to Physicians' Bill

(*O'Leary v. Croghan (S. D.), 173 N. W. R. 844*)

The Supreme Court of South Dakota, without explaining the special nature of this case, says that the only question presented for determination on this appeal was the constitutionality of Chapter 150, Laws of 1911, which reads:

Nothing in this chapter shall be so construed as to exempt any personal property from mesne or final process for laborers' or mechanics' wages or physicians' bills, or for the necessities of life, including only food, clothing and fuel, provided for the debtor or his family, except property absolutely exempt Provided, that in case of physicians' bills or for necessities of life, there shall also be exempt household and kitchen furniture, including stoves, of the debtor, to an amount in value not exceeding \$400, and also two cows; provided, however, that the collection of physicians' bills shall not be enforced by legal process in less than six months from the accruing thereof except when the debtor is about to remove from the state.

Stated somewhat differently, under the provisions of this chapter, the amount of a debtor's exemptions depends on the nature of his debts. As against certain classes of claims he may not be allowed any exemptions at all, except such as are denominated as absolute exemptions, while as against other claims he may be allowed additional exemptions to the extent of \$750 worth of personal property, as provided by Section 2659, or the alternative exemptions enumerated in Section 2660, of the code. A corresponding discrimination is made as between different classes of creditors. A laborer or mechanic may satisfy his claim for wages out of any property of the debtor, except that made absolutely exempt, and may have immediate execution. A physician and one who has supplied the debtor with the necessities of life must leave the debtor \$400 worth of household and kitchen furniture, including stoves, and also two cows, in addition to his absolute exemptions; and the creditor who furnished the necessities of life may have immediate execution; but a physician cannot have execution until six months after accruing of his claim.

None of these discriminations are authorized by Section 4 of Article 21 of the state constitution, which provides that:

The right of the debtor to enjoy the comforts and necessities of life shall be recognized by wholesome laws exempting from forced sale a homestead, . . . and a reasonable amount of personal property, the kind and value of which shall be fixed by general laws.

On the contrary, such discriminations are expressly prohibited by the provisions of Section 18, Article 6, that "no law shall be passed granting to any citizen, class of citizens or corporation, privileges or immunities which upon the same terms shall not equally belong to all citizens or corporations. The discriminations that have been attempted by the legislature may be wise and in the interest of the public at large, but until the constitution has been changed the legislature is without authority to make them. The court is satisfied that, in enacting Chapter 150, Laws of 1911, the legislature exceeded its constitutional power, and that said law is void.

THE CHICAGO SOCIETY OF INTERNAL MEDICINE

Thirty-First Regular Meeting, Held Feb. 23, 1920

The President, DR. JOSEPH A. CAPPS, in the Chair

The Bacteriology of Epidemic Influenza

DRS. JAMES C. SMALL and FRED STANGL: *Bacillus influenzae* was found in 100 per cent. of our cases studied in our first series; pneumococcus Type I, none; Type II, one; Type II atypical, five; Type III, one; Type IV, nine; total positive for pneumococcus, sixteen, or 72.7 per cent. Hemolytic streptococci were found in two instances, or 9.1 per cent.

A second group comprises forty-five cases of acute influenza which were studied by the throat and sputum cultures only. These cultures were made on brown blood agar, and no attempt was made to identify organisms other than *B. influenzae*. This organism was obtained in forty-three of these cases, or 95.5 per cent. Six of this number had throat cultures only. The two cases negative for *B. influenzae* were in this group of six.

Among thirty controls, *B. influenzae* was demonstrated twenty-one times, or 70 per cent. The relative high incidence of *B. influenzae* in this group is comparable to the findings during the pandemic of 1918, and may be regarded as illustrating the wide dissemination of these organisms during epidemic periods.

In a second series, twenty-six patients in the tuberculosis hospital were studied. These patients were hospitalized before the epidemic. *B. influenzae* was found in nine instances, or 34.6 per cent. The findings in this group may be regarded as comparable to the incidence of *B. influenzae* during interepidemic times.

A group of thirty-two cases studied presents the bacteriology of the pneumonia of influenza, as it occurred among cases chosen at intervals throughout the course of the epidemic. The results of this study have been: Pneumococcus Type I, two; Type II, one; Type II atypical, six; Type III, five; Type IV, thirteen; total, twenty-seven, or 84.4 per cent. Hemolytic streptococci with pneumococci, one instance; with no pneumococci, five; total six, or 18.7 per cent. *B. influenzae*, twenty-four instances, or 75 per cent.

Those types of pneumococci occurring in the mouths of normal persons were found in practically 90 per cent. of the pneumococcus pneumonia of this group. The parasitic types I and II occurred infrequently: Type I only twice, and Type II once. These findings are in accord with those reported for the pneumonia of 1918. The hemolytic streptococcus occurred in approximately a fifth of the cases. It should be emphasized that in cases studied early in the epidemic this organism was not found. All instances in this group in which hemolytic streptococci were found appeared among the cases studied within the latter half of the period.

Ward surveys for hemolytic streptococci were made on three occasions at about ten-day intervals in several of the wards. These surveys were instituted to determine the

hemolytic streptococcus situation in the wards rather than to follow the bacteriology of individual patients. The sheet cubicle system and a definite plan for preventing contact infections within these wards was practiced.

One of the wards had a high incidence of hemolytic streptococci at the time of the first survey. Isolation of patients carrying hemolytic streptococci did not prevent its further dissemination within this ward, and on the third survey twelve of twenty-two patients, or 54.4 per cent., had hemolytic streptococci in their throats. Four empyemas (all due to hemolytic streptococci) developed in this ward. Some cases of otitis media and one case of frontal sinusitis also developed in this ward. The bacteriology of these was not determined.

The other ward had an incidence of hemolytic streptococcus carriers of 16.7 per cent. on the first survey. Ten days later, on the second survey, it had only 3.3 per cent. On a third survey, only four patients remained in this ward, and two of these were positive. Two empyemas appeared in this ward, neither due to the hemolytic streptococcus. Several cases of otitis developed here also, of undetermined bacteriology.

These studies are too incomplete to enable one to draw conclusions, but it is a striking circumstance that, in the ward in which hemolytic streptococci were most prevalent, only hemolytic streptococcus empyemas developed, while in the other ward, no hemolytic streptococcus empyemas developed.

Observations on Green-Producing Cocci of Influenza

DR. RUTH TUNNICLIFF: During the recent influenza epidemic the majority of observers have isolated green-producing diplococci from the sputum and from material obtained at necropsy. The organisms were generally classed as Type IV pneumococci on account of their being soluble in bile and not agglutinated by pneumococcus serums. Pneumococci of Types II, III and more rarely I were isolated also. *Streptococcus viridans* and nonhemolytic streptococci were isolated by Keegan, Nuzum, Blanton and Irons, and others; but the colonies were not described, so that it is not possible to identify them with the other strains of streptococci. Other workers, notably Mathers, MacDonald, Rosenow, Howell, Anderson and Jordan, isolated a peculiar green-producing streptococcus from the nasopharynx, sputum, blood and necropsy material. This streptococcus was isolated by the late Capt. George Mathers at Camp Meade at the very onset of the epidemic at the camp and during the first and second days of the disease. He isolated this streptococcus from the sputum in 87 per cent. of the 110 cases of influenza and the complicating bronchopneumonias. The Pfeiffer bacillus was isolated also in 58 per cent. of these cultures. The coccus was cultivated from necropsy material in the six cases examined, the Pfeiffer bacillus from five.

I made immunity experiments with the Mathers coccus to determine its relation to influenza and the complicating pneumonia. The serum was examined for opsonins, as this antibody is usually easily demonstrated in streptococcus infections. The serum of patients with acute influenza was examined daily for its opsonic power. On the first day of the disease the opsonic content was low. On the second or third day it rose well above normal, remaining high a day or two.

Severe cases of bronchopneumonia following influenza were also examined. The serum showed little or no opsonins for the Mathers coccus. The negative phase in these influenzal pneumonias for this green-producing streptococcus is much more pronounced than is generally observed in other acute infectious diseases. The serum of the patients that recovered showed, as the symptoms subsided, a high opsonic content.

These changes in opsonins in influenza and influenzal pneumonia were specific for the Mathers coccus, no fluctuations being observed with the Pfeiffer bacillus, *B. influenzae*, *Micrococcus catarrhalis* or *Streptococcus hemolyticus*. Agglutination experiments with this streptococcus were negative.

It does not seem possible to determine definitely the etiologic relation of the Mathers coccus to influenza and its complications. At Camp Meade, Md., it was the prevailing organism during the onset and height of the epidemic. It was the micro-organism which appeared with the onset of influenza, Pfeiffer's bacillus having been present in the respiratory diseases for several weeks previous. In Chicago, Dr. Jordan found this coccus present in a few more cases than the Pfeiffer bacillus. When present, the coccus was always found in the early stages of the attack and was more closely associated with the pneumonia cases than the Pfeiffer bacillus. However, Dr. Jordan found the Mathers coccus present in colds and tonsillitis infections in about the same proportion of cases as influenza, while the Pfeiffer bacillus was here found less frequently.

My experiments, and later those of Rosenow, Howell and Anderson, show that the serum of convalescent influenza and influenzal pneumonia patients shows definite specific opsonins, agglutinins and complement fixation bodies for the Mathers coccus, which indicates that it played at least some part in the reaction in the epidemic and was of wider distribution than has been commonly recognized.

Evidence for and Against the Use of Vaccines in the Treatment of Influenza With and Without Pneumonia

DR. ERNEST E. IRONS: Before a remedy, whether prophylactic or curative, is recommended for general use, its powers and limitations should be well determined: (1) It should be of itself harmless, and should be of proved value; (2) if not altogether harmless, its value should be such that the advantages far outweigh the risk involved in its use; (3) if harmless of itself, it may still be dangerous in that it gives a false sense of security, and thereby prevents the institution of other more effective measures of prevention or cure. A common example of the latter type is the fumigating of a house while the resident, a carrier of the disease, goes at large. In estimating the value of vaccines in the prevention and cure of respiratory disease, several factors are commonly neglected:

1. Controls: No one today would accept a report on a Wassermann test unless he were assured that in making it, all necessary controls were used. In estimating the value of vaccines in groups of patients inoculated with them, it is not sufficient to base conclusions on impressions. Statistics, to be available for safe conclusions, should be based on large series of cases with like numbers of controls under identical conditions. This has not usually been the case in reports available in the literature; and when these are carefully examined the fallacy in the argument is usually recognizable.

2. Results of Animal Experiments: Animal experimentation, while fundamental and a necessary preliminary in biologic investigation, does not afford the final proof of value of a remedy for man. Because an immune serum for example contains demonstrable antibodies and will protect a mouse from fatal infection in a dose of 5 c.c., it does not follow that this serum will be effective in man in the same or even fivefold dose. In the same way, because the injection of a relatively large quantity of bacteria into animals produces demonstrable antibodies, it does not follow that the injection into man of an allowable amount of the same bacteria will afford protection against the corresponding organisms; nor is the amount of demonstrable response the same for all organisms. Even in the often quoted example of typhoid vaccination, the immunity is only relative, and though usually sufficient, fails when large numbers of bacilli are ingested.

During the recent periods of influenza epidemics, it has been proposed to prevent influenza by the inoculation of vaccines containing streptococci, pneumococci and the Pfeiffer bacillus, and this method has been widely practiced. The amount of vaccines used in this way is enormous—usually under circumstances which preclude the drawing of any scientific conclusions from results obtained. In the first place, the evidence that the Pfeiffer bacillus is the cause

of influenza is extremely weak. It is true, that in recent weeks it has been found quite constantly in respiratory infections in Chicago. This prevalence was noted last year in some localities in the East, and in still other Eastern communities the same workers using the same methods were unable to find this bacillus. The Pfeiffer bacillus has also been found for years in diseases which have nothing to do with influenza, and at times when clinical influenza was not present. It is evident that the Pfeiffer bacilli in the vaccine cannot, therefore, be expected to contribute anything specific to the supposed protection from influenza.

The question then may be asked whether on clinical grounds any protection is afforded. Among the few adequately controlled reports available is that of McCoy, who inoculated a portion of the inmates of an institution and subsequently found an incidence of influenza among them equal to that in a like number of uninoculated controls.

If vaccines as used failed to protect against influenza, did they protect against the later pneumonia? The organisms of the secondary pneumonias varied greatly in different parts of the country, and in the same community at different periods of the epidemic, and so a vaccine prepared for use in one community might not have any specific relation to the prevalent type in another. To argue the importance of some unknown nonspecific elements in vaccines and other proteins in the treatment of disease is to cast aside one of the most important guides in the study of immunity. So far as I have been able to find, there is no conclusive evidence that previous vaccination had any effect on the incidence of pneumonia following influenza.

Of the other factors that had an enormous effect on the incidence of pneumonia, early hospitalization was the most important in the army and in civil practice. Patients already in hospital, such as those in surgical wards, frequently contracted influenza, but rarely pneumonia. Nurses who remained on duty after the onset of influenza developed pneumonia in twice as many cases as did nurses who went to bed at the first symptoms.

As has been the practice in recent years, a variety of substances, such as peptones, vaccines, liquor formaldehydi and mercurial salts, were injected intravenously in patients suffering from pneumonia, usually without any attempt at comparison with control cases. Some of the discussions of events following the injections would be amusing if it were not for the serious import to the patients. When in an occasional case the chill and thready pulse resulting from the administration of the vaccine is followed by a permanent defervescence, the event is described with as much detail as if sudden defervescence were not of almost daily occurrence in other groups of pneumonias not under such treatment. The effect of these administrations in hastening the fatal issue is not usually discussed.

In view of the very doubtful efficacy of vaccines in prophylaxis of influenza and its subsequent pneumonia, it is believed that further popularization of this method of control of influenza is undesirable. The use of vaccines and other proteins intravenously is dangerous, as well as being of extremely doubtful value.

DISCUSSION

DR. E. O. JORDAN: My own work in regard to influenza is incomplete, and my opinions are somewhat unformed at the present time. As regards the Pfeiffer bacillus, we made some observations both in the 1918 epidemic and in the epidemic just passing. I got the impression in 1918 that there was undoubtedly a good deal of variation in the frequency of the finding of the Pfeiffer bacillus according to the group that was examined.

We had several groups under observation in our laboratory work and we found a good deal of difference both in the frequency of occurrence of the Pfeiffer bacillus in individual cases and as regards actual numbers of Pfeiffer bacilli in different cases. That observation has been confirmed by our findings in the present epidemic. The frequency of occurrence of the Pfeiffer bacillus in cases of acute respiratory infection is by no means very convincing as to the rôle this organism plays in the primary infection. I confess to

being very much impressed by the work done by Park's laboratory on the lack of unity in the different strains. In one case, for instance, he describes his findings with six strains isolated from six members of one family, all coming down with typical influenza at about the same time, and these six strains from six different members of the family were all different immunologically. The serum of one strain would not agglutinate any of the others. This observation has been confirmed independently by Fleming in England, and those who have worked with the agglutinated serums have found considerable diversity in the reactions obtained.

There are different kinds of Pfeiffer-like organisms in the throat, both in normal persons and in different kinds of respiratory infection, and it may be that we shall have to sort out the different kind of bacteria. I do not believe the criteria usually employed for the identification of the Pfeiffer bacillus are sufficient to permit us to place these organisms in one group. We have certainly different kinds of organisms that have gone under the name of Pfeiffer bacilli, and it will take some time to sort them out.

In the last twenty-five years quite a number of cases have been put on record of meningitis in which the Pfeiffer bacillus has been found in pure culture, and these cases have been regarded as due to this bacillus. If the Pfeiffer bacillus was the cause of meningitis in the 1918 epidemic, we might suppose there would be, in all events, some increase in the number of cases of meningitis due to the Pfeiffer bacillus; but there has not been anything of that sort. Again, attempts made to produce influenza in human beings with injections of pure cultures of Pfeiffer bacillus have been unsuccessful in the vast majority of cases.

A word about the very interesting organism Dr. Tunnicliff has described. In the 1918 epidemic we found the Mathers organism, which had an extraordinary degree of virulence. It killed mice and sometimes guinea-pigs more rapidly than any other bacteria I ever got out of the respiratory tract. We have been examining the flora of ordinary colds and have not found the Mathers cocci in these cases; so when the first case of influenza appeared last month we looked with great interest to see whether the Mathers coccus was present, and much to my surprise we did not find it. We have not found Mathers' cocci in anything like the number we did in 1918.

With reference to vaccination or vaccines, in connection with the commission, financed by the Metropolitan Life Insurance Company, on respiratory diseases, of which I am a member, some observations and experiments are being carried on at the present time with a mixed vaccine, and it is hoped that before long we shall be able to give you the results of the work of this commission.

DR. DAVID J. DAVIS: The work that has been going on in the last year or two emphasizes the fact that the hemophilic organisms and the so-called influenzal bacillus are very widely distributed. In normal individuals the percentage varies anywhere from 10 to 40 or 50 per cent., which means that one person out of every three, four or five normally harbors these bacteria, and this percentage persists in epidemic times as well as in interepidemic times, as shown by the work of Lord and a number of other investigators. This organism is more widely distributed and more frequently the cause in all sorts of respiratory diseases, both acute and chronic, than any other. We have known for a long time that the bacillus occurred in practically 100 per cent. of whooping cough cases, and these organisms are not more dangerous, although they are distinctly different. It occurs commonly in measles cases, in various kinds of pneumonias, in meningitis cases, meningococcic infections, and in bronchiectases, pulmonary tuberculosis, and so on; consequently, the mere fact of the occurrence of the organism in a high percentage of cases, taken by itself, is not a criterion of any great value in considering it as an organism of etiologic importance in connection with this disease or any other disease. Pfeiffer, for instance, nearly forty years ago found the organism known by his name in practically 100 per cent. of cases, yet in the last year or two in Germany they have had great difficulty in finding the organism in a small number of cases. Pfeiffer's early work was supported gen-

erally by German investigators, yet in the 1918 epidemic, generally speaking, these German investigators had not been able to find the organism and had generally taken a stand against it as the cause of influenza.

As to the presence of hemolytic streptococci in the throat, I should like to call attention to the point that an error may creep in in making cultures from throats. Hemolytic streptococci are virtually constant in all throats in which tonsils are present. They can be found deep in crypts of the tonsils, and unless this fact is considered, reports of throat cultures in which hemolytic streptococci are found may be misinterpreted. These organisms are developing in the crypts from time to time and are passing out into the throat. They are quite virulent for animals, and they are obtained from empyema cases or from the blood in fatal cases.

DR. A. M. MOODY: I had occasion to examine material from many cases of influenza in France during the epidemic of 1918. The first cases occurred the latter part of August, 1918. It was impossible to differentiate those cases clinically from the cases we saw later. We made a bacteriologic examination of the material from the lungs, trachea, bronchi and sputum, and in nearly every case we found hemolytic streptococci in pure culture. About the middle of September the bacteriologic findings seemed to change and we began to find more influenza bacilli and green-producing streptococci similar to the organism described by Dr. Tunnicliff. In the first part of October we began to get patients from the states. During the epidemic we found more and more influenza bacilli. In November we found a mixture of all sorts of organisms, particularly influenza bacilli, and streptococci in the fatal cases. In the fatal cases we found large numbers of streptococci in the alveoli, so that none of these organisms can be put down as the cause of the disease. I do not believe we are any nearer the solution of the cause of the disease today than we were quite a while ago.

DR. JOSEPH A. CAPPS: In visiting the different base hospitals in France it was interesting to see the difference of opinion among bacteriologists as to the different organisms they found. In a group of hospitals having the same type of cases clinically one bacteriologist would find influenza bacilli, another pneumococci, and another streptococci. There were many places in which influenza bacilli were not found, and it was thought by some of the chief surgeons that the bacteriologists did not know how to find them; yet many of these bacteriologists were experts, and the reason they did not find influenza bacilli more frequently was that they were not there.

Does one attack of influenza confer immunity? I have seen several cases recently which lead me to believe that it does not. One patient in particular had leukopenia, respiratory symptoms, great prostration, and other symptoms associated with influenza, and recovered. This patient went to Florida and again developed a fresh attack. Another patient, after having recovered from the primary attack of influenza, went to California, and several weeks after the first attack had a second one. I presume that one can say this was a recurrence or perhaps a relapse, such as we have in typhoid fever cases.

DR. THEODORE TIEKEN: I have a strong conviction that vaccines are absolutely useless. I find that practitioners are using them for both prophylactic and curative purposes. They are using two or three different varieties of vaccines in the same cases so as to have what they call a polyvalent vaccine. In a town in an adjoining state I found one practitioner who was using Sherman's, Parke, Davis & Company's and Mulford's vaccines in the same case. When this patient developed pneumonia he switched to No. 38 or to No. 36. By the time I got there the patient developed marked tympanites and diarrhea, so that the practitioner had a colon vaccine ready to use. This is merely an example of what is going on and as showing the indiscriminate use of vaccines.

DR. ELLIS KIRK KERR: In connection with immunity, we were struck by the epidemic, Sept. 20, 1918, which ran for about six weeks. During that time we had about 6,000

cases of influenza in our camp of 35,000 or 40,000 men. About two days before the armistice, a troop movement started from the rural districts in Minnesota. The men were collected in Minneapolis and sent to Chattanooga. The men who were attacked with influenza were dropped off the train at different places. They had the same type of influenza that was prevailing in the camps. While the original epidemic was on, the ward attendants, nurses and physicians were coming down with the disease in the same proportion as the men in the camps. When this batch of men came in from Minnesota there was practically no extension of the disease. This group was isolated in camp, and the very ill patients were sent to the hospital, but there was practically no spread in the hospital from this group of cases. It would seem as if the disease had gone through the camp and picked out all the susceptible men.

DR. BERNARD FANTUS: Last year I had quite a number of patients who, two or three months after the primary attack, developed another attack. In the meantime, they had been entirely well. I have had a few patients that have developed a third attack about two months after the second attack. I think all practitioners have noticed the fact that in this year's epidemic many individuals were taken sick who were sick with influenza last year. Again, some patients who had severe attacks last year have had mild attacks this year, and vice versa.

So far as the vaccine treatment is concerned, vaccines cannot be of great value because we do not know what particular organisms are concerned in the causation of the disease.

Miscellany

PROCESS OF CANNING RIPE OLIVES

Because of the number of cases of botulism lately reported after the eating of canned ripe olives, there is naturally some speculation as to the processes involved in preserving this fruit. From a recent summary (*Am. Food J.* 15:26 [Feb.] 1920) it is learned that while practices vary slightly certain procedures have been generally adopted by olive packers. The fruit is permitted to ripen on the trees, care being exercised to start picking before the olives are overripe. After the olives have been gathered by hand, they are transported to the packing plant, there first to be sorted by sizes, then put through repeated washings and conditionings for variable periods depending on the quality and condition of the fruit, the seasonal temperature and the technical details in vogue at the particular plant. In some plants the olives are kept in agitation during these procedures by means of the ordinary hand paddle, while compressed air jets serve the same purpose under more modern practices. The olives are first immersed in clear water in cement or wooden vats for two or three weeks, in order to prepare the skins for the subsequent steps in the process. They are then subjected for from eight to twelve hours to the action of a solution of caustic soda, $2\frac{1}{2}$ ounces to the gallon of water. After exposure to the air until their coloring is uniform, the olives are again immersed in a solution of caustic soda, $1\frac{1}{4}$ ounce to the gallon of water, for a period of from eight to twelve hours. The second caustic treatment is to abstract the bitter properties of the fruit and is followed by washing in clear water until all traces of the lye have been removed. The olives are next immersed for one or two days in a brine solution testing 9 or 10 points on the salometer, after which they are deposited in bins in the canning room. Women operators then pack them in cans, rejecting at this time all imperfect or soft fruit. The cans are filled with brine testing about 12 points on the salometer at a temperature of 175-180 F. and are subjected to an exhaust process of 185 F. before sealing. The fruit is next cooked at 224 F. for from twelve to thirty minutes depending on the size of the containers, and is permitted to cool naturally. No effort is made by any of the canners to control accurately the temperature of the solutions in the various processes.

*Histologic Study of Spleen of Rabbit Under Heightened Phagocytic Activity. W. H. F. Addison, Philadelphia.—p. 437.

Nature of Osteoclasts.—The observations recorded by Arey were made on developing membrane bone of human and pig embryos. He concludes that the multinucleated giant cells known as "osteoclasts" probably include several morphologically similar but developmentally distinct elements. In the earliest stages of bone development, and to a certain extent in later stages, osteoclasts apparently arise from the confluence of the mesenchymal cells and connective tissue of the marrow. The chief source of osteoclasts, however, is from old osteoblasts and bone cells. Depleted, basophilic osteoblasts coalesce to form multinucleate masses. These syncytial elements become typical osteoclasts when their cytoplasm assumes an oxyphilic stainability. All intermediate tinctorial stages are demonstrable. True oxyphilic osteoclasts also exist in cytoplasmic continuity with basophilic osteoblasts. Increase in size and nuclear content results from the engulfing of osteoblasts met in the path of resorption and from bone cells which are ingested as the bone matrix is resorbed. Osteoclasts undergo retrograde changes and ultimately disappear through extreme degeneration. Only indirect and insufficient evidence points to the osteoclasts as the active, specific agents of bone resorption. That they are merely degenerating, fused osteoblasts, in Arey's opinion accords better with the known facts.

Spleen and Phagocytic Activity.—The cycle of changes associated with the phagocytic activity of the splenocytes of the rabbit was followed by Addison. He noted that when washed pigeon corpuscles are injected intravenously, they are rapidly hemolyzed. The hemolysis of the pigeon blood results in the liberation of great numbers of bone marrow cells, mature and immature. These are caught within the spleen, and quickly begin to be ingested by the splenocytes. The splenocytes grow with their increased contents, until at the sixteen hour stage they reach a very large size. As many as twenty cells are visible in a 4 microns section of a splenocyte, measuring 55 by 23.4 microns. As digestion proceeds, the splenocytes become smaller, and at the forty-eight hour stage they are much reduced in sizes some being not much larger than normal. Of the products of hemolysis of the pigeon blood after a single injection, little remains within sixteen hours. In the spleen, the splenocytes have an increased amount of iron containing substances, while the endothelial cells show, for the most part, very little. The comparatively small results seen within the phagocytic cells follow from the rapid reduction of the foreign blood corpuscles to particles of a very small size, and from the short time in which these fragments remain within the blood stream. In this special experimental procedure, where cells and cell fragments are the stimulus to phagocytosis, the splenocytes are the first to act, and they continue to act as the main phagocytic agents.

Effect of Strain on Heart Rate and Blood Pressure.—

Dawson and Hodges report the results of their experiments to determine the immediate effect on the heart rate and blood pressures of exercises of strain. By "exercises of strain" is meant those muscular efforts which are performed with the glottis closed and which tend to compress the chest, thereby causing a rise in intrathoracic pressure. The two forms of strain studied were the Valsalva experiment and lifting. In the Valsalva experiment, the systolic pressure rose rapidly, primary rise. This was followed by an extensive fall. On cessation of the Valsalva effort there was a moderate rise of the systolic pressure. Lifting was characterized by changes in systolic blood pressure essentially similar to those which occurred in the Valsalva experiment. When the Valsalva or lift was modified, the usual picture was somewhat changed. The effect on the heart rate of greatly prolonging the Valsalva experiment was to decrease the intensity of the effort and with this the extent of the changes in the heart rate. When the Valsalva experiment experienced a series of interruptions, consisting of a single gasp each, the systolic blood pressure rose with each gasp from 10 to 20 mm. above normal. When a lifting experiment experienced similar interruptions, the changes of heart rate were less in extent than would otherwise occur even when the weight lifted was greater in amount. Observations were also made during parturition. During a labor pain in the anesthetized and tracheotomized rabbit, the mean blood pressure experienced changes (rise followed by fall) which are attributable to the changes in peripheral resistance due to uterine contraction and subsequent relaxation. The respiration also changed, decreasing in amplitude to a standstill in the inspiratory phase and then gradually returning to normal.

Cause of Gastric Secretion.—The existence of two classes of bodies causing gastric secretion is suggested by the authors. Whether these bodies are extractives from special tissues or hydrolytic cleavage products has not been determined. The investigation in the distribution of gastrin bodies has been temporarily abandoned for the more promising studies into the chemical nature of the product derived from the gastric mucosa.

Hydrogen Ion Concentration of Urine.—Talbert claims that intense exercise from fifteen to twenty minutes' duration increases the hydrogen ion concentration of the urine. A man subjected to the heat of a sweat cabinet for fifteen or twenty minutes will, in a large majority of cases, void a urine of higher hydrogen ion concentration. If muscular exercise follows immediately on subjection to heat, or vice versa, it is impossible to interpret the results.

Treatment of Back Injuries.—From the study of thirty cases of vertebral fractures without cord symptoms and from a much larger series of simple back strains, Marshall concludes that spinal bone grafts are suited best for well-to-do patients who will be considerably benefited by slight or moderate improvements in their physical conditions. Results of surgical methods are not beneficial enough uniformly, and chances of fair or excellent recoveries are so good in healthy young adults without operation, that spinal bone grafts are not warranted in the majority of workmen's cases. Spinal grafts reinforce the posterior group of spinal ligaments and usually strengthen spines, at least to slight degrees. There are some dangers that unavoidable injuries to muscles and ligaments which result from surgical procedures may weaken backs more than inlaid grafts strengthen them. Mechanical appliances are required very commonly for considerable periods of time even after successful grafts; and results of this combination are presumably better often than either single method of treatment alone. Slight degrees of bony fracture in healthy young subjects are fairly well recovered from without operation in six months or less at times; and severer grades of bony impactions occasionally are followed by complete restorations of back functions without operations several years after dates of injuries. Treatments of back injuries, perhaps, should be directed primarily toward restoring strengths in muscular and ligamentous tissues because these are phases of treatment which are usually overlooked and neglected; but pathologic conditions in crushed vertebrae should be appropriately treated by immobilization and protection in ways universally approved in treatment of fractures. Treatments of musculoligamentous defects should include use of various therapeutic agents, according to physiologic requirements of the tissues in question. There should be use of mechanical braces to reinforce muscles and to offset temporarily the extra mechanical strains due to faulty postures or anatomic deformities. Physical therapeutic agents, massage manipulations, and exercises should be employed as well as internal medical measures. The latter rectify vascular defects and influence muscles and ligaments through the qualities of circulating blood. Continuous exclusive use of any one of these methods is unjustifiable for very long periods, and they should be alternated and

combined with due regard to established physiologic principles of alternate rest and activity known to be best for muscles and ligaments.

*Treatment of Chronic Ulcers. F. E. Stowell, Worcester.—p. 176.
Case of Metacarpal Fracture. S. S. Dearborn, Nashua, N. H.—p. 178.

Present Needs of Tuberculosis Campaign.—Hawes does not believe that more laws in regard to tuberculosis are needed. Overzealousness on the part of local health boards, he says, has done harm to many patients and prejudiced their physicians strongly against reporting future cases. Education as to the need of reporting tuberculosis, on the one hand, and tact on the part of the local authorities, on the other, are what will solve this problem. Nor does he believe that antispitting laws accomplish much. Here again education as to habits of cleanliness and decent living and not more legislation is what is needed. The harm done by the careless spitter and the incorrigible consumptive, he says, is, after all, very slight. What has been accomplished in reducing the mortality from consumption during the past twenty-five years, and what shall be accomplished in the future is not because by means of sanatoriums a number of patients have been cured, nor because the spread of infection has been prevented by providing beds for advanced consumptives, but because the gospel of right living has been spread. It is what is being done to solve the tenement and housing problem; it is the school and factory inspection and hygiene; the prevention of industrial diseases; it is a pure milk and water supply, thereby eliminating typhoid and other acute infectious diseases; open air schools, boy scouts, health crusaders—it is all this, and not efforts directed solely to the tubercle bacillus or the tuberculous individual that is ridding the world of tuberculosis.

Diet Reduction with Retention of Protein to Relieve Glycosuria in Diabetes Mellitus.—The theories underlying the diet reduction method are outlined by Fenlon. By keeping the protein intake of the diet at a necessary level, the tendency to a development of acidosis is decreased as the patient does not have to burn his own body fats. Protein is needed to replace that lost by the wear and tear on the tissues during the metabolic changes of the body. Chittenden's standard of 0.12 gm. of nitrogen per kilogram of body weight is necessary to the body during a diet reduction. This amount of protein is increased in this method because of the altered metabolic changes in diabetes. With the protein intake maintained at a definite level the percentage of carbohydrate in the diet would be relatively decreased. Under preparatory treatment to fasting the protein and fat are both reduced, leaving the carbohydrates relatively high. The tolerance of the patient is more easily and quickly determined. There is less complaint of hunger on the part of the patient by this method of reducing diet. The protein in the diet, by maintaining the serum protein in the blood, possibly aids in the nutrition and functioning of the kidney during the diet reduction. Of fifteen patients treated according to this method, 100 per cent. were discharged sugar and ketone free.

Treatment of Chronic Ulcers.—After a preliminary washing of the ulcer with soapsuds, 1:2,000 mercuric chlorid and alcohol, as much dead material as possible is removed with forceps and the base of the ulcer is very gently curetted to remove slough and exudate. The ulcer is then cleaned again with alcohol and painted with a 50 per cent. tincture of iodine. The patient is then connected with the negative pole of the static machine, the positive pole being grounded, and the static breeze and sparks thoroughly applied to ulcer and surrounding areas. According to Stowell, this usually relieves all pain at the first treatment and can be so regulated as not to be unpleasant. The object of all this is to

remove stasis and stimulate healing. A dry dressing or, occasionally, in the judgment of the operator, a boric ointment dressing is applied and then the leg is bandaged. This Stowell considers is a most important part of the treatment and he says it must be done correctly. The method is described in detail.

Pyloric Obstruction and Gastric Tetany.—The authors point out that when the pylorus is obstructed and the gastric juice with its hydrochloric acid is constantly removed, there ensues a decrease in the chlorin of the plasma. There is a consequent increase in the alkali reserve which becomes extreme. The electrical excitability of the nerves is, in general, heightened and there are spontaneous twitchings and in most cases violent convulsions which lead to death. All of this can be prevented by constantly furnishing a large supply of chlorids. The authors injected from 50 to 100 c.c. of a 2 M (117 gm. in a liter) sodium chlorid solution intravenously. It is less easy to cure the condition by the administration of chlorids. The convulsive movements are not exactly like the twitchings of the tetany of parathyroidectomy in which they found no heightened alkali reserve, but they can be produced by the injection of sodium carbonate or bicarbonate. Since these convulsions can be stopped or prevented by sodium chlorid, it remains a problem as to what becomes of the excessive base sodium and as to the specific need of the chlorin ion. Further experiments are contemplated to settle these points.

Acute Cholecystitis Complicating Typhoid.—Reid and Montgomery report a case of a large typhoidal empyema of the gallbladder in a girl, aged 8 years, and review eighteen cases of typhoid fever in persons less than 15 years of age who either died from or who were operated on for complications arising in the gallbladder. The authors believe that the low operative mortality (only one of these patients died) justifies operation when there is grave doubt as to the nature of the condition of the gallbladder. Acute typhoidal suppurative cholecystitis should receive immediate surgical treatment, for in such cases rupture of the gallbladder may occur and thus lessen many times the chances of recovery. The best treatment is said to be cholecystectomy.

Roentgen-Ray Studies of Seminal Vesicles and Vasa Deferentia.—Young and Waters believe that they have demonstrated that catheterization of the ejaculatory ducts and radiographic study of the canal system above may be carried out with ease, and that it furnishes a ready and satisfactory method of determining the condition of these structures. The process is apparently without danger. In about fifty cases in which the instruments and thorium solution have been introduced for varying distances into the vasa deferentia and seminal vesicles, they have never encountered an epididymitis or any other deleterious sequels. The method is described in detail.

Self-Eventration of Large Abdominal Hygroma.—A child, 2 years old, was brought to Halsted to be tapped for ascites. The child's abdomen presented the typical ascitic picture. In making a short incision in the midline, the peritoneum

was accidentally pricked. Immediately there protruded through the prickhole a vesicle hardly larger than a mustard seed. The little bladder, slowly increasing in size, soon covered the abdomen, and finally in saddlebag fashion fell over the child's flanks, a broad, flat isthmus of sac-contained fluid stretching across the now scaphoid belly from one great bag of water to the other, both of these resting on the bed sheets. The wall of this great cyst was of filmy thinness. The midline incision was then lengthened and a search made for the pedicle, about which several small cysts were found to be grouped. All of these seemed to have their origin in the great omentum—embryologically, in the posterior mesogastrium. An independent cyst, about as large as an orange, seemed to be contained between the layers of the duodenal mesentery, the continuation of the stomach's mesentery or posterior mesogastrium. This cyst was so adherent to the mesenteric vessels that Halsted feared its removal might imperil the circulation of the bowel; hence he stitched its wall to the parietal peritoneum, and in a few days opened and drained it. The child made a prompt recovery. Twenty-two years later, examination of the abdomen revealed nothing abnormal, except, perhaps, a little tenderness in the region of the appendix.

Upturned Edge of Liver in Gallbladder Infections.—Halsted regards this as a diagnostic sign of some value. He has never noted this upturned or everted edge in the absence of signs of infection of the gallbladder, but is not sure that it may not occur with hydrops vesicae. More than once this sign has enabled Halsted in a debatable case to make the correct diagnosis.

Fate of Bacteria in Upper Air Passages.—Bloomfield found that *B. coli* and *Staphylococcus albus* swabbed on the tongue or nasal septum usually disappeared within twenty-four hours. *B. coli* and *S. albus*, introduced into tonsil crypts could be recovered after somewhat longer intervals. In no case was a permanent carrier state set up. Inert particles disappeared at about the same rate of speed as the bacteria. The organisms probably disappear because they are mechanically removed more rapidly than they multiply. The disposal of *B. coli* and *S. albus* illustrates a mechanism radically different from that effective in removing *Sarcina lutea*.

Nonparasitic Hematochyluria.—Hampton reports a case of nonparasitic chyluria that has persisted over a period of nine years in a young woman whose health was below par. She had a mitral stenosis that had given symptoms at intervals for more than ten years. Her chief complaint had been general weakness with frequent syncopal attacks. Just how much of her disability depended on one or other of these conditions, could not be determined. Apparently, her kidney function was unimpaired. There was no evidence of renal or pulmonary tuberculosis. The leak in the lymphatic system was located in the right kidney. On starvation or a fat-free diet, the urine became fat-free, blood cells and albumin persisting. Posture influences did not control the amount of lymph leakage. Increased water intake and urine output increased the "fat loss."

Myoma of Uterus with Degenerative Changes.—In Brady's case a large cystic mass extended out into the broad ligament, and arising from the posterior surface of the uterus and extending into the left side of the abdominal cavity there was a large myoma. The cyst was multilocular, heart shaped, had a bluish color and extended downward from the lower surface of the uterus. On the inner and lower side of the cyst, about 2 cm. from the external os of the uterus, there was in the vagina an opening about 2 mm. in diameter. A small probe was introduced into this opening and a definite canal dissected out. Brady says that such a canal is in exactly the correct location for one of the rather rare embryonic remains of Gaertner's duct. Cross sections of the duct showed a musculature resembling that found in an artery and no epithelial lining. The cyst was made up of several smaller cysts, each of which was filled with grumous material. In one of these smaller cysts was a well developed polyp. Sections from the cyst showed it was a myoma showing degenerative changes.

Poisoning by Nicotin.—The five cases of poisoning reported by McNally have occurred from taking insecticides containing nicotin by mistake for whisky.

Ectopic Adenomyoma of Uterine Type.—The ten cases reported by Mahle and MacCarty were extra-uterine and extratubal tumors diagnosed at the time of operation as adenomyomas. These growths contained glandular portions resembling typical uterine mucosa, surrounded by a fibrous connective tissue, and smooth muscle stroma, the latter in varying amounts. The distribution of the tumors was as follows: umbilicus, 1; abdominal wall, 2; sigmoid, 1; groin, 2, and rectovaginal septum, 4. Clinically these tumors gave no consistent group of symptoms on which an accurate diagnosis could be made. Of the ten patients, six gave a history of symptoms directly referable to the tumor.

Early Diagnosis of Typhoid and Paratyphoid Infections.—Goeckel claims that it is possible to obtain and identify typhoid and paratyphoid bacilli in the urine by agglutinins before the blood shows a positive Widal reaction or a typical cell count. By this means a prompt report may be given than if blood culture is resorted to. It is a more definite method of identification of the infection than is identifying agglutinins in the patient's blood serum. It is also more positive and eliminates reliance on the Widal reaction of blood serum. Goeckel suggests that it should be resorted to whenever possible in patients who may have a natural or acquired agglutinating capacity due to previous infection or through the use of vaccines.

Congenital Obstruction of Posterior Urethra.—Twenty-four authenticated cases of congenital obstruction of the posterior urethra recorded in the literature are reviewed by Young and his associates, and twelve cases, admitted to the Johns Hopkins Hospital, are reported in detail. Three distinct types of congenital obstruction, all more or less valvular in construction, so placed that the concave surface of the valve is directed upward, thus bringing about an obstruction to the outflow of urine. In the great majority of cases, symptoms of the condition are manifest during infancy or early childhood. Symptoms of the condition are those arising from obstruction to the outflow of urine, together with the symptoms resulting from renal destruction, induced by back pressure and infection. The history of symptoms of urinary obstruction in male children in the authors' opinion should always suggest the possibility

of this condition. The presence of a distended bladder, and particularly of residual urine, is further indicative of obstruction. This possibility is further strengthened by obstruction in the posterior urethra to the passage of a catheter. Much information regarding the character and exact location of the valves and the renal damage resulting therefrom may be obtained by urethroscopy, the use of the roentgen ray, and renal function studies. The treatment of the condition is surgical, and consists of the removal of the obstruction. This may be accomplished in certain cases by the passage of a sound, with the forcible rupture of the valve; in certain other cases the obstruction may be removed by the urethrotome or by urethrotomy. Of the operative procedures, the selection of the suprapubic or perineal route will be governed by the personal preference of the operator. In infants and young children the suprapubic method has proved very satisfactory, the valvular obstruction being removed by its forcible rupture with a sound, its division with a rongeur, or its removal by scissors or cautery. In adults the condition is treated in most cases by intra-urethral methods.

Bladder in Secondary Syphilis.—Twenty-four male patients with active secondary syphilis were selected by Zimmermann and Levy for this investigation. Nine cases presented macular syphilides, twelve a papular eruption and in three the eruption was pustular. In eighteen there were lesions on the mucous membrane of the mouth and pharynx, or moist lesions about the anus or on the scrotum. In no case were urinary symptoms present, and examination of the urine was negative, except for a few shreds in the first glass in a few cases of chronic urethritis. No striking bladder changes were discovered. In ten cases slight vascular changes were noted in the region of the trigone in the form of a delicate ramifying network, and on the bladder wall itself as an increase in the caliber of the vessels. The vascular changes were not considered significant. None of these cases presented either papular or ulcerative lesions.

Effect of Feeding Prostate.—By feeding prostate gland to the larvae, the metabolism of the tadpoles was stimulated and their metamorphosis was hastened. In other words, the tadpoles developed legs earlier than normally and were soon transformed into frogs. At the same time the size of the tadpoles was not diminished and, indeed, in many cases the tadpoles also increased in size. This effect was produced by feeding the desiccated prostate of the ram of bulls and of human prostate. Macht believes that such a phenomenon speaks strongly in favor of an internal secretion of the prostate gland.

- *Administration of Arsphenamin by Retention Enema. J. L. Mandracchia, Brooklyn.—p. 144.

Empathic Index and Personality.—This term was coined by E. B. Titchener and deals with the idea of reading oneself into an animate or inanimate object. Brill regards this index as being a new and quick method of observing a person's mode of adjustment. He speaks of a racial, national and biologic empathic index and relates his experience in determining the index in different persons, on the basis of "Tell me your empathic index, and I will tell you who you are." For instance, Brill has found that a nickname given by classmates or friends usually shows the person's empathic index. The woman's empathic index always shows the type of man that appeals to her.

Administrations of Arsphenamin by Retention Enema.—Mandracchia describes a method by which arsphenamin is given in an enema. The solution of arsphenamin is prepared in the usual way, diluting it to between 200 and 250 c.c. The

apparatus consists of a glass cylinder of a capacity of about 300 c.c., connected at one end with a rubber tubing having a glass window and a stopcock, and a rectal tube of sufficient caliber so that the fluid can flow easily and swiftly. The solution having been prepared and placed in the cylinder, and the air having been expelled, the patient, if a male, is allowed to assume the genupectoral position, and if a female, the lateral or Sims position. After the rectal tube has been introduced into the rectum for 4 or 5 inches, the solution is allowed to flow into the rectum by gravity after the stopcock in the rubber tube has been opened. As a rule, the average patient can hold this enema from twenty to twenty-four hours. In exceptional cases, it has been held for four days. Arsphenamin seems to have a constipating effect on the intestinal tract. Where a patient cannot retain the enema, it has been the custom to give a dose of the tincture of opium or paregoric by mouth. In children this is a standing rule. The enema having been given, the patients are sent to bed and allowed to remain in bed for about four hours, instructing them to change their position at frequent intervals. Reverse persistalsis can be more readily facilitated when the foot of the bed is elevated. In adults, the initial dose is 0.3 gm. and every dose thereafter is 0.6 gm. The enema can be given either once or twice a week, all depending on the condition of the patient. By giving the enema twice a week it is believed that the spirochetes are kept in a constant arsenic saturation and thus the duration of the infection is materially shortened. The ideal time to give these enemas is in the evening. During the course of arsphenamin enemas, the patient should undergo a course of active mercurial treatment. No sequels, such as headaches, nausea, vomiting, fever, dizziness, or subsequent nitroid crises acting destructively on the eyes, kidneys and liver, or a fatal termination have been observed by Mandracchia.

- *Surgical Problems of Pancreas, Report of Cases. C. E. Roeder and A. L. Nielson, Omaha.—p. 23.

Malignant Sarcomas.—Emmert reports a case of tumor on the posterior surface of the right thigh midway between the trochanter and the popliteal space, about the size of a large orange in which a clinical diagnosis of sarcoma was made and operation advised. The tumor was removed. The pathologic diagnosis was simple fibroma with large connective tissue cells. Six weeks after leaving the hospital a streptococcus infection started in the scar and spread over the entire leg and thigh. This subsided in two weeks. One week later there developed rapidly on the median surface of the left ankle a tender inflammatory mass which was thought to result from the recent infection. This persisted for several weeks and then the inflammatory condition subsided, leaving a firm mass which was recognized as a sarcoma. The mass was removed five months after the first one. The pathologic diagnosis was fibromyxosarcoma, spindle and round cells. The second patient was only 2 months old. At the time of birth, a mass the size of a pigeon's egg was noticed on the thoracic wall. The mass was excised later. The microscopic diagnosis was fibromyxosarcoma.

Surgical Problems of Pancreas.—Roeder and Nielsen report three cases: congenital pancreatic cyst; infectious pancreatic cyst and acute pancreatitis.

Wassermann Contradictions.—Wolbarst is of the opinion that the Wassermann test and the gonorrhea fixation test should be made by at least three serologists working independently; the serum should be taken simultaneously and sent to the different laboratories under identical conditions; one serologist is not to be depended on, however capable he may be. Three serologists will agree in approximately 53 per cent. of Wassermann tests and approximately 42 per cent. of gonorrhea fixation tests. That is, the chances are about fifty-three in a hundred that three serologists will agree on any given serum. They are more likely to agree in the negative cases than in the positive cases. At all events, it is well to devote more study to the clinical features of all cases and trust not quite so implicitly on laboratory workers for a diagnosis.

Dental Syphilitic Chancre.—Goodman reports a case of syphilitic infection contracted at the site of tooth extraction.

New Method of Inserting Bone Graft for Correction of Kyphosis.—The method which Grantham proposes is to make a transverse incision, 1 inch long, just below the posterior spinous process of the affected vertebrae, extending through the supraspinous ligament. A thin osteotome, made with a reverse curve, is introduced as far as the base of the spinous process; the process is sheared in a direction parallel with the spinal canal; the two processes above the vertebra are cross sectioned in the same manner without the withdrawal of the instrument. The osteotome is then withdrawn and inserted in the opposite direction, and two spinous processes below the affected vertebra are cross sectioned, in a similar manner; a graft of sufficient length, from one-half to three-quarters inch in width, is secured; the capsular layer of periosteum is removed in such manner as to leave as much of the intervening osteogenic layer of cells as possible on the graft. The graft is now introduced into the tunnel thus prepared for its reception; if the skin incision requires a suture, it is placed subcuticularly, with catgut armed with two needles, so that the needles pass from within outward in passing through the skin. Grantham claims for his method that the graft is placed in direct bony contact, the endosteal surface to the stumps of the cross sectioned posterior proc-

esses, near the laminae; the periosteal surface, its fibrous capsule removed and as much as possible of the osteogenic layer of cells preserved, is pressed firmly by the freed ends of the processes, held in situ by the uncut lumbodorsal fascia, and supported literally by the muscles of the back.

*Routine Treatment of Malaria in Uganda. J. A. Taylor.—p. 113.
*Comparison of Two Methods of Administering Arsenobenzol Compounds in Syphilis. H. E. Gibson.—p. 14.

Early Diagnosis of Pulmonary Tuberculosis.—Besides placing dependence on the family history, previous history, as of pleurisy and hemoptysis, subjective symptoms, such as gradual loss of flesh or of constantly increasing languor, lassitude, tiredness, inaptitude for work, indigestion, dyspepsia, retching, anemia, slight evening pyrexia, feeling dull and tired in the evenings, objective signs, such as deficient expansion, impaired resonance on percussion, cogwheel respiration, posttussive crepitations, and the roentgen ray, Beattie attaches much importance to the tuberculin diagnostic test. He prefers to use Koch's T. A.; 1:1,000 dilution, 1 c.c. hypodermically.

Treatment of Malaria.—Most of the cases of malaria met with in Uganda, Taylor says, are of the simple subtertian form without complications. The routine treatment adopted by him in these cases was, calomel, in an average dose for an adult of not less than 5 grains, followed in some hours by a saline. Quinin hydrochlorid, 5 grains by mouth, one hour after the saline. This was usually about 7 a. m., and between this time and noon three more doses of 5 grains each were given at more or less regular intervals. On subsequent days, until the temperature had remained normal for twenty-four hours, 20 grains were given daily in the same manner, the first dose at 6 a. m., or as soon as the patient was awake, and the last dose at noon. After the temperature had been normal for twenty-four hours, the quinin was reduced to 15 grains daily—5 grains before the morning, midday and evening meals. This was continued for one week and then reduced to 10 grains daily—5 grains morning and evening. Ten grains daily were continued for a fortnight, and then only 5 grains were given each evening for two months. Acetphenetidin, in 5 grain doses, up to 15 grains daily, for headache alone, or acetylsalicylic acid in the same doses, if complaint were also made of pains in the limbs and body. Under this treatment the temperature usually remained normal after the third day, but occasionally, especially if a first attack, after four or five days; no complications occurred in any cases from the effects of the quinin or malaria; there were no recurrences of the fever during the three months' treatment, and attacks only occurred later when some definite fresh infection had taken place.

Administration of Arsenic Compounds in Syphilis.—The two courses of treatment given by Gibson were a concen-

trated course, which was completed in five or six weeks, and a "prolonged course," which lasted about eight weeks. Advantage seems to lie with the prolonged course, partly owing to the lesser incidence and violence of reactions, and partly because the total results are better than with the concentrated course; this especially applies to secondary cases.

 Twenty Years of Plague in India; Outbreak of 1917-18. F. N. White.—p. 190.

Yield of Bacterial Substance for Area Growth.—Harvey claims that yield of bacteria, as measured by surface growth, is a reasonably good approximation to moist bacterial weight and is very easily estimated. Weight of bacteria moist presents a considerable degree of direct relationship with weight dry. There is, however, a greater variability of weight moist for constant area of surface than there is of weight dry. The weight of bacteria in the dried condition would, therefore, appear to be the only satisfactorily accurate measure of quantity of bacterial antigen.

Dried Bacterial Antigen.—Not only can a dried antigen of bacterial substance be prepared easily, but it can be used with safety in animals by intravenous and intraperitoneal injection. Harvey found that such an antigen conserves its power of production of agglutinins for a long period. It is of extremely small bulk; is easily measured by weighing; and is capable of being dispensed in mixture with other similar antigens in any proportion desired.

Antiberiberi Vitamin Content of Peanut Meal Biscuits.—Greig's investigation shows that the ground nut (peanut) meal biscuit is as rich as the 15 per cent. atta biscuit in antiberiberi vitamins. Hence, the ground nut meal, whether in the form of bread or biscuit, would be suitable to form part of an "emergency" or other ration for issue to the troops.

Charcot-Leyden Crystals in Feces in Amebic Colitis.—After examining on an average about 500 stools a month, Acton has come to regard the presence of Charcot-Leyden crystals to be an almost certain indication of the existence of an amebic colitis and not to be associated with helminth infections. In the absence of amebas, he does not hesitate to diagnose the case as amebic dysentery when pus, mucus and Charcot-Leyden crystals are found, and the results obtained by treatment with emetin justified the conclusion.

Culture Medium Suitable for Growth of Organisms Used in Vaccines.—Various types of culture mediums were prepared and examined by Norris with a view to the determination of their nutritive value as regards the growth of *B. typhosus* for vaccine purposes. Of the various meat mediums at present in use, those prepared by means of a tryptic digestion appear to be much more nutritive than an ordinary beef peptone medium or than those prepared by acid hydrolysis. The addition of nutrose and casein appears to have no great influence on growth unless added to a particularly nonnutritive medium. The addition of a comparatively small amount of hydrolyzed nutrose to a poor medium increases the growing power to the level of an ordinary trypsinized medium. Glucose seemed to inhibit growth. Mediums obtained by the tryptic hydrolysis of nutrose, press cake from ground nut, and casein give material equal in nutritive value to that obtained from meat. In examining the nutritive value of these mediums, concentration of substrate appeared, within limits, to be of greater importance than time of hydrolysis.

 Clinical Applications of Solidified Carbonic Acid. T. Sato.—p. 17.
 *Wassermann Reaction of Aqueous Humor. G. Okazaki.—p. 17.

Wassermann Reaction of Aqueous Humor.—In the aqueous humor of the eyes of syphilitics, except when inflammation of the eye existed, Okazaki succeeded in demonstrating a Wassermann reaction in the proportion of 1:200 or even 1:600 part of the blood contents. In the presence of inflammatory diseases of the eye, the antibodies appeared in an even higher concentration. The Wassermann reaction in the aqueous humor occurs just as soon as it does in the circulating blood.

- *Pancreatic and Intestinal Infantilism. T. G. Moorhead.—p. 1.
 The Criminal as a Patient. C. E. McQuade.—p. 11.

Pancreatic and Intestinal Infantilism.—In one case cited by Moorhead the apparently primary pathologic change was a catarrhal condition of the colon, and probably also of the small intestine, and, in consequence, the author regards the case as one of undoubted intestinal infantilism. Other changes present were probably secondary and resulted from the inanition produced by the bowel condition. The second case reported appears to be a further confirmation of Byron Bramwell's view, that pancreatic infantilism is a definite entity.

 *Lupus of Upper Air Passage: Report on 128 Cases. R. Webber.—p. 7.
 Sphenoidal Sinus Empyema in Cerebrospinal Meningitis. E. A. Peters.—p. 11.

Lupus of Upper Air Passages.—Webber believes that in the vast majority of cases of lupus, the condition first appears in the nose. This was the case in 113, or 88 per cent., of the 128 cases studied by him. The disease began either on the anterior part of the nasal septum, on the mucous membrane of the outer wall of the nose and close to its junction with the septum, or on the anterior end of the inferior turbinate. In a certain number of cases there was an extension of the disease to the mucosa of the hard and soft palate, the pharynx or larynx, without evidence of skin lesion, but in sixty-nine, or 52 per cent., of the cases, skin involvement was noted on the face. Glandular involvement occurred in forty-eight cases, the glands most frequently affected being those of the submaxillary chain. As worthy of note Webber calls attention to the fact that in twelve of these cases there were present scars following operations for old submaxillary gland trouble. He infers that at the time of such operation the disease within the nose causing the gland enlargement was present but overlooked. One of Webber's patients has been under treatment for his lupus for thirty-two years! In the treatment of lesions on the palate and alveolar process, the best results were obtained from curettage and the application of lactic acid (75 per cent. solution) or the electric cautery. For lupus of the nose, Pfannenstiel's treatment was distinctly helpful. This consists in curettage and packing the nasal cavities with gauze soaked in hydrogen peroxid, and sodium iodid internally. In lupus of the epiglottis and the laryngeal mucosa, removal of the diseased area with cutting forceps often has resulted in a cure, or, at least, arrest of the disease. The roentgen rays have been used largely in the past in the treatment of the associated skin condition, but at the present time they are used only in selected cases. Webber emphasizes that no matter what treatment is selected, only the closest cooperation between the patient and the person in charge of the case will produce the best results.

Etiology of Thrush. A. Castellani.—p. 17.

*Case of Appendicitis in Native of Solomon Islands. N. Crichlow.—p. 22.

Appendicitis in Solomon Islands.—According to Crichlow, appendicitis is a rare disease among the natives of the Solomon Islands. During five years' experience among these natives he has seen only one case. The case in question was a young missionary girl, who after being "Christianized" and "Europeanized" left off eating native foodstuffs and used to eat European foodstuffs. Crichlow says he cannot help feeling that the European foodstuffs and her life in civilization played some part in the development of her attack of appendicitis, as appendicitis is unknown among the natives living solely on native foodstuffs.

Value of Cystoscope as Means of Diagnosis in Urology. A. S. Roe.—p. 25.

*Isolation of Organism Resembling Paratyphoid Group. A. Dean.—p. 27.

*Case of Septicemic Anthrax Successfully Treated by Intravenous Serum Therapy. E. N. Bateman, N. H. Fairley.—p. 32.

*Case of Rupture of Liver, with Recovery. L. Doyle.—p. 32.

Isolation of Organism Resembling Paratyphoid Group.—From the urine and feces of five cases, no two of the same disease, Dean isolated an organism of the coli-typoid group, which gave unusual biochemical reactions in the sugars. The organism was smaller than *B. typhosus*, being more of a coccobacillus in appearance. It varies from 1 to 2 microns in length. It stained easily with the usual anilin dyes, but was gram-negative. The organism does not ferment dulcitol, lactose, inulin or adonite, while, on the other hand, it ferments saccharose, mannite, maltose, glucose, sorbitol, raffinose and arabinose. Its gas producing powers are considerable, particularly on saccharose, glucose and sorbitol. In arabinose and raffinose its action is changeable. New cultures give acid and slight gas formation. Some subcultures only give acid reaction. Its action on litmus milk differs widely from the usual nonlactose fermenters. For the first four days no change is noted, except that on the second day the alkalinity of the litmus milk is more exaggerated, the milk becoming intensely blue. On the fifth day, the milk assumes an acid reaction. This continues until the tenth day, when clotting of the milk occurs. On the fifteenth day, the milk clears, but still retains its acid reaction. In its agglutination reactions, this organism appears to be more closely linked to *B. paratyphosus* B, than *B. paratyphosus* A or *B. typhosus*.

Septicemic Anthrax Successfully Treated by Intravenous Serum Therapy.—In the case reported by Bateman and Fairley, anthrax bacilli were demonstrated in quantity in the seropurulent discharge from the excised pustule, and on the fifth day of the disease, blood culture yielded a positive result. The energetic administration of a large quantity of Sclavo's serum culminated within twenty-four hours in a critical fall of temperature, in a complete recovery from all toxic symptoms, and in a rapid amelioration of the local lesion itself.

Traumatic Rupture of Liver.—A boy, aged 8 years, sustained a rupture of the liver from being run over by an automobile. The outstanding features of the case were the thoracic type of breathing, the anxious expression of the child and the history of very severe trauma. Micturition occurred shortly afterward and perfectly normal urine was voided. A provisional diagnosis of a ruptured abdominal viscus was made by Doyle, and the evidence suggested that the lesion would be found in the spleen or the left lobe of the liver. The general appearance of the child was indicative of an injury much more serious than what was compatible with the physical signs, and it was felt that it would be safer to explore the abdomen immediately rather than to wait. Laparotomy was performed about two hours after admission. On opening the peritoneum, blood stained fluid was encountered, and on retracting the abdominal wall, blood gushed up in startling quantity and with great rapidity. The

issue was traced to the right lobe of the liver. There was a laceration on the anterior surface, commencing on the free edge, about 2.5 cm. lateral to the gallbladder and running vertically for about 5 cm. A long strip of iodoform gauze was packed as tightly as possible into the wound, and the end was brought out of the incision. Four large abdominal packs were inserted between the liver and the diaphragm over the tear. Transfusion of physiologic sodium chlorid solution and of the father's blood was done. About seventy hours after operation, under light ether anesthesia, the packs were removed, drains were inserted and the wound was closed again. No further hemorrhage occurred. The lesson Doyle draws from this is that when there is a possibility of a solid abdominal viscus being damaged, it is generally safer to explore at once rather than to await the classical symptoms of hemorrhage.

Nov. 8, 1919, 17, No. 21

*Syphilis in South Africa. A. Pijper.—p. 323.

Successful Treatment of Case of Sleeping Sickness. W. A. Murray.—p. 326.

Case of Urethral Hemorrhage. H. T. Mursell.—p. 328.

Syphilis in South Africa.—In order to determine the prevalence of syphilis among the population of South Africa, Pijper subjected the blood serum of fifty persons born in South Africa, and who apparently were healthy, to the Wassermann test. Five were found to have acquired syphilis at some period of their existence. In other words, according to these figures, 10 per cent. of people born in South Africa, while apparently healthy, are infected with syphilis. As none of these persons presented any symptoms, Pijper assumes that the disease was in the latent stage at the time of their examination. It is a well known fact that only about 50 per cent. of syphilitics will exhibit a positive Wassermann reaction, while in the latent stage. Consequently, 20 per cent. of the population of South Africa are infected with syphilis while seemingly enjoying good health. If the percentage of latent cases is 20 per cent. it may safely be assumed that the total percentage of persons infected with syphilis is somewhere between 20 and 25 per cent.

*Diagnosis of Different Forms of Slow Pulse. L. Bard.—p. 385.

*Phono-Phlebograms. J. de Meyer and V. Gallemaerts (Brussels).—p. 395.

*Digitalis in Tuberculosis with Low Blood Pressure. R. Burnand.—p. 419.

Diagnosis of Slow Pulse by Inspection of Veins.—Bard states that the diagnosis of the nature of bradysphygmia is usually made from the pulse tracings, but that this is possible merely from inspection of the jugular pulse wave. He explains how the characteristics of the pulse wave permit the false bradycardias from coupled rhythm of the ventricles to be distinguished from true ventricular bradycardia, and further distinguish between the three varieties of the latter. Thus in the majority of cases simple inspection of the venous pulse serves to differentiate the six different forms of slow pulse with regular rhythm.

Phonophlebogram.—De Meyer and Gallemaerts have continued their research published in 1914 on the graphic recording of the sounds that accompany the venous pulse, or at least those sounds which are perceptible on auscultation of the bulb of the jugular vein. They use the Einthoven apparatus as for cardiography, and record a whole series of complex sounds from the auricle and ventricle systoles and the duration of the silences.

Digitalis in Pulmonary Tuberculosis.—Burnand is medical director of the Sanatorium populaire at Leysin, and he here expatiates on the advantages of prolonged administration of digitalis in pulmonary tuberculosis with abnormally low blood pressure. He gives it irregularly, three days out of every ten, and has been convinced of the benefit therefrom in cases in which the myocardium still retains some of its vitality. In the advanced stages the heart is unable to respond.

- *Inherited Syphilis and Dystrophies. V. Hutinel and H. Stévenin.
—p. 5.
Children's Asylums, etc., Should Be in the Country.—J. Camescasse.
—p. 37.
*Present Status of Nephritis in Children. J. Comby.—p. 41.

Inherited Syphilis and Dystrophies.—Hutinel and Stévenin review the whole field of special and general dystrophies from inherited syphilis, and emphasize its predilection for the liver, spleen, brain and glands. Its effect on the endocrine glands may be responsible for the development of such opposite conditions as dwarfism and giantism, obesity and extreme leanness, severe rachitis, chronic rheumatism, etc. Treatment requires not only measures against syphilis but also the specific organotherapy for the endocrine gland involved. They discuss the anatomic lesions for which the inherited syphilis is responsible, commenting in particular on the constant abnormal changes in the bone marrow, lungs and heart. The latter is very rarely directly affected by the syphilis; it seems to pass by the larger blood vessels and heart in children, and act merely on the smaller vessels. They cite some cases of genital infantilism in which the development of the organs had not only been arrested but sclerosis had invaded them and crushed out the noble elements. In other cases the organs undergo actual retrogression; this is particularly likely in the pluriglandular cases, especially those in which pituitary or thyroid disturbances predominate. This clinical picture may be traced to other chronic infections and intoxications besides syphilis, but is more common with the latter, as the morbid process is more apt to act on several of these glands at once. This is not inevitable, however, as some of the glands may become pathologic only secondarily to the first ones involved.

Nephritis in Children.—Comby reproduces nearly the whole of Hill's article on this subject in the *American Journal of Diseases of Children*, April, 1919. Comby comments on it that it "mirrors his own experience and ideas." . . . "Dr. Hill," he adds, "has observed large numbers of cases and has observed them well. His descriptions bear the stamp of truth."

- *Medical Treatment of Acute Amebic Disease of the Liver. F. Françon.
—p. 21.
*False Tuberculosis. A. Jacquemin and M. Dubreuil.—p. 23.

Medical Treatment of Acute Amebic Disease of the Liver.—Françon emphasizes that the differential diagnosis of acute amebic hepatitis may be puzzling when there is associated malaria or the clinical picture resembles typhoid, pleurisy, gastro-enteritis or cholecystitis. Instances of each have been published. Radioscopy is useful when the ameba cannot be detected in the stools, as happened in 15 of his 28 cases, and in 16 of Ravaut's 21. Medical treatment is necessary even when an operation is contemplated. In the 88 cases Françon has compiled, emetin was given in 72 cases; neo-arsphenamin in 2, and both in 12. He regards the combination as most promising. When exploratory puncture shows a young focus, with creamy, reddish pus, with well preserved leukocytes and no fatty degeneration, the focus can usually become resorbed under medical measures alone. But with dead pus and associated infection, resorption is practically impossible and the focus will have to be mechanically cleared out; secondary infection is not amenable to emetin treatment. Medical measures are liable to fail also if the abscess is larger than a mandarin orange. Recurrences can be treated with the medical measures anew. The results in the 88 cases

he has compiled fully confirm the efficacy of emetin in amebic disease of any kind. It seems to be even more effectual when the focus is in the liver rather than in the bowel, as is easily explained by the fact that the encysted forms of the ameba seldom get into the liver, and superposed infection is the rule in the intestines.

False Tuberculosis.—Jacquemin and Dubreuil review their four years of sanatorium experiences in respect to false and factitious pulmonary tuberculosis. They warn of the danger of incriminating tuberculosis when the patient has merely a bronchitis of nasal origin or exhibits the lung phenomena of mitral stenosis or the respiratory disturbances common in certain forms of liver disease, or has interlobar pleurisy with a fistula into a bronchus. There may be frequently recurring or continuous bronchitis when the nose is more or less stopped up. "Beware," they say, "of mouth breathers; examine the nose before the chest." Stones in the gall-bladder may induce a pleural reaction, pains in the shoulder, tendency to hemorrhages, and occasional waves of fever and general depression that may be mistaken for pulmonary tuberculosis, especially when there is a cough. The liver cough may deceptively simulate a lung cough, and the right tracheobronchial glands may enlarge under the influence of the cholecystitis. The laboratory findings may be the only clue in such cases. An old interlobar pleurisy with a fistula into a bronchus is almost certain to be mistaken for pulmonary tuberculosis unless it is noticed that the fever occurs in the morning instead of the evening. Another sign is a tendency to hippocratic fingers. This, they declare, is always the expression of a pleural lesion. It is a synonym, they say, for interlobar pleurisy when it occurs early. With pulmonary tuberculosis it is exceptional and tardy.

As the demobilized men know that a sputum containing tubercle bacilli is like a government bond in insuring a certain income from the state, all kinds of tricks are practiced to impose the diagnosis of pulmonary tuberculosis. To avoid fraud, the man is examined on waking. He is given two or three swallows of tea, and is told to expectorate in the sterilized spit-cup given him for the purpose. His hands are carefully washed beforehand. This method averts fraud, but it is tedious and makes a number of examinations necessary. Among the tricks described is the effort to show a rapid loss of weight; the man at the first weighing artificially increases his weight.

Bulletins de la Société Médicale des Hôpitaux, Paris

Dec. 12, 1919, 43, No. 36

- *Edematous Rash from Neo-Arsphenamin. G. Milian.—p. 1055.
Epidemic of Probable Dengue in Troops in Near East. Pagnier and O. Couffon.—p. 1059.
*The Blood in Typhoid after Vaccination. P. Armand-Delille and others.—p. 1063.
*Senile Wrinkled Skin in Children. A. Souques.—p. 1074.
*Injection of Air for Radioscopy. P. Emile-Weil and Loiseleur.—p. 1077.
*Spirochetal Jaundice. Lortat-Jacob and Deglaire.—p. 1077.
Pott's Disease in Woman of Seventy. P. Merklen and H. Schaeffer.—p. 1079.
*Gas Gangrene in Typhoid. Weinberg and Françon.—p. 1084.

Rash with Edema and Desquamation After Arsphenamin.—The man in Milian's case developed the rash, with edema of the eyelids, etc., resembling that with Bright's disease, after he had been taking a long course of neo-arsphenamin. The urine was constantly normal, except for urobilinuria. Ramond has encountered a similar case, the scarlatiniform eruption developing after the sixth injection. The syphilis was of only a few weeks' standing. The edema in face, arms, and legs was extreme, but there was no fever and the general condition and appetite kept good. The man became transiently deaf in one ear, probably from extension of the edema to the eustachian tube. This edematous rash persisted for about two months, the pruritus keeping up to the last. Ramond remarks that this toxic eruption with edema is not so rare as might be imagined from the literature, but instances of it are not published as a rule.

Blood Findings in Typhoid and Paratyphoid After Vaccination.—The findings in 350 cases in soldiers and civilians

in the near East are given. They suggest that paratyphoid bacilli seem to acquire greater virulence in subjects vaccinated against typhoid. The authors comment that this seems to confirm the wisdom of polyvalent vaccination.

Geroderma in Children.—Souques recalls another case of loose, flabby, corrugated, senile skin in a child. Variot says that he has also encountered two cases of the kind.

Roentgenography After Injection of Air.—Weil and Loiseleur comment on the double advantage from injection of air after an effusion is evacuated. It not only has a therapeutic action but aids materially in the diagnosis by rendering much more distinct the outlines of the pleura, peritoneum or joint involved in the process.

Spirochetal Jaundice.—The case was typical in the robust young man, but there was in addition intense diffuse pruritus throughout the three weeks of the disease, and the urine contained bile salts; there was also bradycardia—all testifying, Lortat-Jacob says, to retention of the products elaborated by the kidney cells.

Typhoid Gangrene.—The typhoid in the young man ran a rather severe course without intestinal complications. Two days after defervescence, symmetrical patches of gangrene developed on the thigh; they were arrested by a gas gangrene antiserum, but the patient died the third day. Weinberg and Françon remark that if the stools or blood had been examined for anaerobes, the antiserum could have been used earlier, and the patient might have been saved.

Dec. 27, 1919, 9, No. 52

*The Mental Stomach. Chavigny.—p. 497.

*Treatment of Scoliosis. Joland.—p. 499.

*Treatment of Deafmutism. G. de Parrel.—p. 504.

Diagnosis of Height of Lesion Causing Spinal Paraplegia. J. A. Barré.—p. 507.

Mental Dyspepsia.—Chavigny declares that we digest with our brains as well as with our stomachs. Gastric digestion is cerebral in large part, and cases of uncontrollable vomiting should be classed as mental dyspepsia, and be treated by psychiatrists after gastro-intestinal specialists have diagnosed the case. He remarks that psychiatrists will realize their finest successes in the *rééducation psychique de ces petits mentaux*. Most of the patients who seek the stomach specialists cherish special fads in regard to eating whole wheat bread or other special diet, or going barefoot, or they have other odd hobbies. It is remarkable, he exclaims, how persons in this category often do well on a diet that a normal person might have difficulty in digesting. He adds that the surgeon must beware of the operative adventures to which this class of patients often seek to entice him. The recent tragic death of Pozzi and of Guinard should warn to refuse to these *petits aliénés* with *troubles cénesthésiques* the operations for which they sometimes clamor. Soldiers with this "mental dyspepsia" should be given rapid mental retraining, with gymnastic exercises and military discipline. In one of the typical cases related, the relapse under emotional stress or extra responsibility confirmed the psychic element involved. The lack of any modification after a useless appendectomy, and the practically normal gastric chemistry testified that the uncontrollable vomiting in the previously healthy officer of 33 was of this nervous dyspepsia type, but more psychic than anatomically nervous.

Abbott's Method of Treating Scoliosis.—Joland insists that Abbott's method for treatment of scoliosis is difficult and dangerous, and should not be attempted except by the few specialists who know the exact indications for it. "The general practitioner should realize that the great majority of scoliotics should not be abbotted."

Treatment of Deafmutism.—De Parrel emphasizes that much can be done by physicians and parents to prepare deaf-mutes for the training in special institutions when they reach the age of 6 or 7. The young child should be given the benefit of hygiene, and of physiologic and surgical measures as the case demands to enable him to profit to the full from the specialist training later. He declares, "absolute deafness

is extremely rare, and if the vestiges of hearing are trained, this is an inestimable gain when specialist treatment is begun." Vision should also be trained to the utmost, as lip reading depends on the visual acuity. De Parrel stresses the importance likewise of preparing the child for *réceptivité pédagogique* so that it will be ready to learn. This is the mother's task, but the physician is the indispensable technical adviser in this, and he should be well posted on what to advise. De Parrel gives minute details of all these preliminary measures, especially those seeking to train in attention; in imitation, and in tactile perception.

*Recent Progress in Tuberculosis. P. Lereboullet and L. Petit.—p. 1.

*Menstrual Equivalents in the Tuberculous. C. Sabourin.—p. 11.

*Miliary Forms of Pulmonary Tuberculosis. A. Pissavy.—p. 19.

Influenza and Tuberculosis. R. Debré and P. Jacquet.—p. 24.

*Diagnosis of Pulmonary Tuberculosis. P. Amenille.—p. 28.

*Sunlight as Factor in Sterilization of Tuberculous Sputum Expectorated on the Street. H. Tecon.—p. 33.

Tuberculosis in 1920.—Lereboullet and Petit say that the prophylaxis and hygiene rather than the medical aspect of tuberculosis engrossed attention during 1919. Among the few communications on the medical features were those on the detection of the falsely labeled tuberculous. Compulsory declaration of tuberculosis seems to have been postponed to the day when the declaration will ensure care and assistance for the tuberculous and his family. Until this can be realized, notification serves merely to pile up statistics. E. Sergent has recently presented evidence that even tubercle bacilli in the sputum do not necessarily prove that the lesions are in process of evolution, and also that the absence of tubercle bacilli is not unfailing testimony as to the nonactivity of the lesions. Radiography throws no light on the age and evolution of the lesions, but a low arterial pressure is the rule in progressing cases. A rise in temperature after muscular exercise does not necessarily mean tuberculosis, as unstable temperature may be observed under various other conditions, digestive, cardiac, etc. They agree with Sergent's dictum that there is no absolutely certain sign which tells whether the tuberculous process in a well appearing person is progressing or not. He may have had hemoptysis on one occasion or a disquieting pleurisy, but has been in apparent health since. Repeated examination, the fixity of the stethoscopic and radioscopic findings, the character of the physical signs, the attenuation of the myotonic reaction, the disappearance of the tenderness at the apex, the normal blood pressure, the intensity of the tuberculin reaction, stability of the temperature, and the repeatedly verified absence of tubercle bacilli from the sputum, form a bundle of proofs on which the diagnosis can be based. The whole secret lies in repeating the examinations and comparing the findings. About 25 per cent. of the tuberculous show roentgen shadows in the fissures between the lobes, but few physicians ever examine for these *localisations scissurales*, and yet they are an important factor in recurring pleurisy. The stethoscope reveals small and inconstant foci of dry rattling, or friction râles, which, associated with intercostal neuralgia and cough, aid in detecting these frequent and benign tuberculous lesions.

Roger demonstrated ten years ago that the absence of albumin from the sputum excluded tuberculosis. A positive albumin reaction is found in many other diseases, but Kronigold has recently published evidence to the effect that the presence of peptone in the sputum is a reliable sign of tuberculosis, as the tubercle bacilli belong to the small group of micro-organisms which by their proteolytic ferments split albumin into albumoses and peptones. Jousset insists that tuberculosis, as we know it, is merely the nodular form of infection by the tubercle bacillus. The latter may induce a wide range of reactions and symptoms, and in both there is first an acute, curable, congestive stage, in which serotherapy is promising. (His method was described in these columns, Aug. 17, 1918, p. 605.) The most important work on artificial pneumothorax during 1919 is stated to be that by Morelli of Montevideo. (One of his recent communications was summarized here, July 19, 1919, p. 235.) He draws the balance sheet with a most favorable balance to the credit of the

procedure in appropriate cases. Lalesque's review of his thirty years of treatment of tuberculosis at a seashore sanatorium is said to be another instructive contribution. He emphasizes the importance of the moisture of the sea air in preventing congestion and hemoptysis.

Menstrual Equivalents in the Tuberculous.—Sabourin describes how the organism seeks to throw off the excess of endocrine secretions that accompany ovarian functioning and which have to be got rid of, unless fecundation occurs. They usually pass off in the menstrual hemorrhage, but in the tuberculous they are liable to make their influence felt first on the points of lesser resistance, inducing congestion and possibly hemorrhage. There may be fever, congestion of the lungs, with hemoptysis, epistaxis, bleeding from hemorrhoids, diarrhea, excessive secretion in nose or bronchi, or there may be menstrual vomiting of bile or transient congestion of the liver, or several of these combined.

The Miliary Form of Pulmonary Tuberculosis.—Pissavy explains why and how we must distinguish between the four forms of pulmonary tuberculosis, the miliary, the nodular, the pneumonic, and the bronchitic or emphysematous form.

Bacteriologic and Radiologic Tests in Pulmonary Tuberculosis.—Ameuille says that he writes this article to convert the few physicians still left who fail to realize the paramount importance of bacteriologic and radiologic examination in every case of disease of the air passages.

Sterilization by the Sun of Tubercle Bacilli in the Street.—Tecon reports research from Lausanne, Switzerland, the results of which demonstrate that sputa expectorated on the roadway under the usual conditions even when exposed to the sun in summer for from two to fifty-two hours, that is, during nine successive days, induced the development of tuberculosis when guinea-pigs were inoculated from them. All the inoculations gave positive results, in one instance after eleven days of insolation. When the sputa had been deposited on snow beaten down in the driveway, the inoculations were all negative except in one instance in which the insolation had been only for thirteen hours. The sterilizing action of the sunshine is thus practically negligible for clumps of sputum such as the tuberculous expectorate.

Presse Médicale, Paris

Jan. 10, 1920, 28, No. 3

*Volvulus of Sigmoid Flexure. E. Forgue.—p. 21.

*Electric Accidents with House Electric Current. A. Zimmern.—p. 25.

*Protecting Coating for the Stomach. F. Ramond.—p. 27.

Volvulus of Sigmoid Flexure.—Forgue emphasizes that the onset is not so sudden with volvulus as with ileus of other cause, and the symptoms are not so violent from the first. There is no vomiting, at least at first, and it is not fecaloid, while urine excretion continues almost normal—all testifying to the low location of the obstacle. The twisted loop becomes distended with gases, and percussion elicits a metallic resonance. The segment of the colon involved, ballooned by the local meteorism, shows an asymmetrical protrusion of the abdomen without peristaltic movements, but these findings are soon masked by the general distention of the intestines. He insists on the tendency to recurrence; the volvulus returned in 10 per cent. of Kuhn's ninety-five cases, and in nearly 16 per cent. of Filipowicz' thirty-two cases. Resection of the twisted loop has given a high mortality, up to 40 per cent., and the technic is difficult. Hence Forgue concludes this comprehensive study with the advice to be content with palliative measures such as colopexy, simple exclusion of the loop by entero-anastomosis, or enterostomy when the obstruction creates a pressing danger.

Mishaps from Domestic Electric Currents.—Zimmern remarks that the lamentable accident which recently cost the life of a colleague has called attention anew to the dangers of electricity even with low-power currents. Electrocutation has occurred with a current of only 110 volts or even less. Conditions in a bath are especially favorable for this, the wet hands and the water clinging to the surface of the body provide exceptionally favorable conditions for conduction of the current if an electric light, or electric

heater, or bell handle, is touched. Jellinek, Lutaud and Fleury have reported cases of this kind, young women being found dead in the bathtub with the metal chain or bulb in their hand. He urges that electric appliances should not be allowed, in bath rooms, within reach of a person in the bathtub. Weiss has reported a case in which a woman was killed in her kitchen as she was holding an electric light in one wet hand and turning on the water faucet with the other. Another woman was killed as she was dusting with a wet cloth the current-distributing apparatus for the electric heating appliances. A man was given an almost fatal shock when he took hold of the chandelier while holding in the other hand an electric light suspended by a wire. Few realize the danger they incur in changing a bulb when the hands or the floor are wet. If there should be some defect in the insulation a serious accident might result. He adds that although he has never heard of an accident of the kind, beyond slight shocks, yet it is well to be warned of the danger, in operating rooms, from manipulating electric lights, cautery, etc., and touching at the same time the water faucet, especially if the floor or walls are moist. The danger from the electric current is for the heart, and the effect is more pronounced when there is an element of surprise. Sleep and general anesthesia attenuate the effect. Rabbits in general anesthesia survive a current that kills at once normal rabbits. Zimmern adds that a number of fatalities have been reported in Germany during the application of Kauffmann's method of treating neuroses, giving a sudden, sharp shock to the patient; he forgets his previous ailments when thus "torpedoed." No explanation could be found in many of the cases for the fatality.

Protecting Coating for the Stomach.—Ramond gives, instead of bismuth, gelose, made from agar and medicated at will, with or without a mixture of gelatin. It is taken like bismuth for the "gastric dressing," one large dose fasting, or half an hour before meals and before retiring. As the dissolved gelose attracts molds, he sometimes used pulverized gelose, 0.10 gm., or a mixture of the same with 0.40 gm. crushed gelatin. This is thrown into a cup of boiling water flavored with peppermint or anise. The boiling is continued for four or five minutes, occasionally agitating; then the fluid is filtered and it is drunk while still hot, before it can coagulate. Or 5 gm. gelose can be boiled gently in a liter of water for twenty or thirty minutes, then passed through fine gauze, and before it cools 200 gm. of some aromatic syrup are added. A tablespoonful of the resulting jelly is dissolved in a cup of very hot water. The patient must change his position to bring this fluid into contact with the inflamed parts of the stomach. This gastric dressing answers the purpose almost if not quite as well as bismuth, and sometimes surpasses it while it has none of the drawbacks of bismuth. Ramond prefers to combine the two, giving bismuth for ten days and then the gelose the rest of the month, or mixing one twelfth of bismuth with the gelose for continuous use.

*Injection of Oxygen to Aid Roentgenography. L. Mallet and H. Baud.—p. 507.

*Cancer of Uterine Cervix. Potherat.—p. 508.

Treatment of Scabies. L. Bory.—p. 509.

Oxygen as Aid in Roentgenography.—Mallet and Baud expatiate on the harmlessness of intraperitoneal insufflation of oxygen, and on the instructive roentgen findings when this is done. The oxygen is harmlessly resorbed in a day or two; acute peritonitis seems to be the only contraindication.

Cancer of Uterine Cervix.—Potherat remarks that cancer on the vaginal aspect of the cervix resembles an epithelioma of the skin in many respects, as the structure of the mucosa of the vagina is more like skin than the mucosa lining the uterus proper. When operative removal was out of the question, he has known of survivals for five, seven and fourteen years after excision of the cancerous tissues down to the hard zone, where the sharp curet was arrested, and then the lesion was cauterized vigorously with a large nummular thermocautery.

*Pulse Findings with "Volume Bolometry." H. Sahli.—p. 2.

*Operations for Goiter. G. Hotz.—p. 6.

*Parallel Skin Tests with Human and Bovine Tuberculin. Bernheim-Karrer.—p. 10.

*Laws Regulating the Multiformity of Symptoms. De Montet.—p. 12.

Research on the Pulse.—Sahli has long insisted that determination of the blood pressure may be misleading unless it is accompanied by a knowledge of the volume of the pulse at the same time. This he estimates by what he calls volume bolometry, and he here describes with illustrations his simple apparatus for the purpose and the numerous instructive findings with it.

Goiter Operations.—Hotz applies on both sides Kocher's method of resecting one half of the thyroid, leaving behind only a small piece. Hotz resects at one sitting nearly the whole of both halves leaving only enough on each side for physiologic purposes. In his 400 operations of the kind, one young man died and necropsy revealed influenza. There was only one other death in the series; this was in a woman of 72, and necropsy disclosed degeneration of the heart. In three cases after-hemorrhage required opening of the wound. The only deficiency symptoms observed afterward were in a young pregnant woman, which subsided under parathyroid tablets, and one case of mild symptoms of hypothyroidism. The recurrent nerves were injured during the operation in 5 per cent. of the first 200 cases; it is not known whether the resulting paralysis has subsided or not, to date. The upper parathyroids are not molested with this technic, but the lower ones are endangered. Other technics sparing more of the gland expose to the danger of recurrence, especially in the quite young. Hotz' operation takes about an hour, but the patient leaves the hospital in about eleven days as the average. He operates under local anesthesia, ligating the four thyroid arteries. Over 12 per cent. of the subjects were only 16 or less. The goiter tissue removed in children averaged 103 gm. He aims to remove all of the thyroid that he can, including the whole of the isthmus. The rectus muscles are severed, and from 60 to 120 ligatures are applied, and sometimes up to half are left in the wound.

Multiformity of Symptoms in Response to Single Stimulus.—De Montet argues that the relations between the various organs and functions are much more extensive than has hitherto been appreciated. The multiformity of the symptoms from a uniform stimulation of the sole, for instance, is evidence of this, he says, as he shows by the findings in a young infant, and in 184 adults, seeking to deduce a general comprehensive law.

*Hemostatic Band in Surgery. U. Nobili.—p. 1019.

Hemostatic Band in Surgery.—Nobili explains the advantages of partly blocking the circulation in the limb or fingers before operating on phlegmons, etc. The aim is more to prevent infectious material being swept into the general circulation during the operation than to avert hemorrhage. In addition to this precaution, Nobili makes a circular incision in the cellular tissue, all in sound tissue, some distance above, in operating on a phlegmon. This cuts off the spread of infectious material by way of the lymphatics, while leaving the arteries intact.

Revista Clínica, Medellín, Colombia

November, 1919, 2, No. 14

The Human Body in Art. Montoya y Florez.—p. 49.

*Permanent Slow Pulse. L. E. Arango.—p. 84.

*Cure of Skin Disease by Intercurrent Acute Infection. J. Restrepo, A.—p. 86.

*Code of Ethics.—p. 90.

Slow Pulse.—The pulse of 36 and the physical signs in the young man whose case is described by Arango, suggested mitral insufficiency with stenosis of the aorta. Considerable improvement was observed under 1 gm. of sodium iodid daily, and sodium cacodylate, with small doses of diuretics and laxatives.

Cure of Dermatitis by Intercurrent Acute Infectious Disease.—Restrepo relates that the ulcerating lesions on the legs had persisted for over three years, rebellious to all measures, but they disappeared completely during an attack of erysipelas. The patient was a woman of 44, otherwise healthy. In a second case of chronic dermatitis of the leg in a young man, it subsided likewise during intercurrent measles.

Code of Ethics.—This is a code presented by the Bogotá Sociedad de Pediatría for consideration at the recent national medical congress. Its special points have been summarized in these columns when published elsewhere.

Revista Médica del Rosario

*Angioneurotic Edema; Two Cases. D. Staffieri.—p. 293.

*Case of Erythromelalgia. A. Boden.—p. 299.

*Chronic Arsenic Poisoning from Drinking Water. C. Alvarez.—p. 311.

Angioneurotic Edema.—Staffieri summarizes the prevailing views in regard to Quincke's edema, in the statement that it is characterized by abnormally exaggerated excitability of certain nerves which have control of the secretion and circulation of lymph. This hyperexcitability is almost always constitutional, the result of "dysendocrinia" (defective functioning of the endocrine glands), with thyroid insufficiency predominating. This excitability is rendered manifest by influences of different kinds, including some which behave like antigens, inducing anaphylaxis. In the first of his two cases, one side of the throat was affected but there was no inflammation. The young man showed signs of thyroid insufficiency and hypogenitalism, and under thyroid treatment there has been no recurrence of the acute edema of the throat. Atropin and a saline purge relieved the immediate symptoms; it was the first and only attack to date. In the other case there had been fleeting edema at various points during seven years. In this latest attack the face alone was involved, and the edema was so extreme that the eyelids could not be closed. As usual, the edema subsided completely in a few days. The patient was a healthy married woman of 35 with two healthy children and negative Wassermann reaction, and there are no signs of derangement of any of the glands of internal secretion.

Erythromelalgia.—Boden describes what he says is the fourth case of Weir Mitchell's disease to be published in Argentina. His patient is a bachelor of 34 with regular habits, healthy until the development of the erythromelalgia fourteen years ago. Four years later symptoms of Raynaud's disease became superposed on the Weir Mitchell set of symptoms, and the man wandered from hospital to hospital in search of a cure or at least some relief. The left big toe had to be amputated about two years ago, and the wound took seven months to heal. Boden cites the three other cases of erythromelalgia in Argentina, and mentions some still unpublished cases and one reported from Santiago de Chile in 1914. The redness and neuralgic pains are not necessarily restricted to the foot. In Cassirer's compilation of 67 cases both feet were affected in 24, both hands in 2, both hands and feet in 17, one foot in 9, and one hand in 4. Auché has published a case in which there was congestion also in the eyes and testicles during the attacks. No acute or chronic infection or intoxication could be discovered to account for the disease in Boden's case, the patient being apparently free from acquired or inherited taint. The only pathologic finding was atony and ptosis of the colon, and great improvement was realized with treatment addressed to the intestines, repose and dieting. One case is on record in which Raynaud's disease subsided completely after resection of the entire colon, and this confirms the close connection between production of toxins in the sagging bowel and the vasomotor centers which regulate the circulation, especially the tropho-secretory neurons and those regulating the peripheral circulation. If the intestinal disturbances do not yield to medical measures, colectomy should be considered. This would break up the sympathetic-medulla reflex arc and remove the source of the toxins, and it is now under consideration in this case. [In J. J. Ferro's 1919 inaugural thesis at the University of Lisbon, the recent international literature on

erythromelalgia is exhaustively cited. The thesis is reproduced in the *Medicina Contemporanea* 37:380, 1919.]

Chronic Arsenic Poisoning from Drinking Water.—Alvarez publishes two further cases of what he calls Bell-Ville disease, as the first cases of this chronic intoxication from arsenic-containing water were observed at Bell-Ville in northern Argentina. The new cases were in men of 25 and 62 and after abandoning the use of water from a certain well, both recovered completely from the severe clinical picture they presented at first. In the young man the liver was predominantly affected, and ascites required tapping twenty-one times. In both the skin showed dark pigmentation, with scattered white and black dots.

*Auricular Flutter. S. Yamada.—p. 308.

*Carbohydrates and the Sugar Content of the Blood. K. Sakaguchi.—p. 345.

Auricular Flutter.—Yamada gives eight double-page tracings of the heart action in a man of 40 with nephritis and auricular flutter. This flutter was up to 230 per minute, and was not influenced by any measures, and it never changed to fibrillation, not even under digitalis. The ventricle could not keep pace with the auricle, and the ratio altered under epinephrin to 3:1, and under atropin to 2:1.

Carbohydrates and the Sugar Content of the Blood.—Sakaguchi publishes here the first report of his research on the nature of diabetes. He has been investigating the influence on the sugar in the blood of the amount, kind and time of ingestion of food. It is evident, he says, that the sugar content of the blood fluctuates even in normal conditions. The range, fasting, in the healthy Japanese was found to be between 0.067 and 0.107 per cent.; the average was 0.088 per cent. There was always distinct hyperglycemia after ingestion of from 70 to 100 gm. of glucose. The hyperglycemia reached its highest point in twenty or thirty minutes, and then subsided, with one or two recurring waves.

Gonorrheal Arthritis.—During the war period Klose noted a woful increase in gonorrhea. Before the war only 2 per cent. of gonorrheal infections presented gonorrheal arthritis, whereas at present Klose estimates the percentage at 10 per cent. There are several causes: personal indifference, forced and improper treatment of the primary infection, and weakened physical condition of patients due to the effects of war. Since 1909, arthrotomy has been carried out systematically in the Universitätsklinik, Frankfurt-on-the-Main, in certain severe types of gonorrheal arthritis. Definite indications for operative intervention have been set up: In a gonorrheal articular effusion, arthrotomy is indicated if, after one puncture, there is a second effusion, accompanied by considerable stretching of the capsule, together with pain, and also when the condition of the joint indicates a beginning subluxation. In phlegmonous and mixed types, arthrotomy is performed: (1) early, in the course of the first few days of a severe phlegmon, if the patient is plainly losing ground on account of pain and loss of sleep; (2) in general gonorrheal infections that arise from a joint infection; (3) in severe primary infections, with genito-urinary complications, which render vigorous, conservative treatment of the joint infection more difficult; (4) in multiple joint infections that cannot all be treated at one time, after careful selection of the joint for the arthrotomy, and (5) as a routine measure, after three weeks, if during this time vigorous treatment has brought about no perceptible remission of the subjective symptoms; in which case a beginning contracture of the joint caused by

an effusion into the flexor tendons should be watched for and guarded against. By means of roentgenoscopy any beginning shrinking of the capsule, atrophy of parts of the joint, or obliteration of joint outlines can be controlled. The beneficial effects of arthrotomy are due to the getting rid of the toxic tissue fluid, and the relief from pressure afforded the tissues. The pain subsides promptly, and the general condition begins to improve at once. The case is thus shortened by many months. Two or three weeks after the operation the medicomechanic treatment may begin. However, in 14 per cent. of the knee joint infections thus treated by arthrotomy, the injuries that the knee had already suffered, proved to be irreparable, and ankylosis was unavoidable.

Preservation of Erythrocytes After Death.—Contrary to the usual view that red blood corpuscles disintegrate within a few days, or at the latest within twenty to twenty-five days after death of the organism, Strassmann found through examination of a blood effusion from the thoracic cavity of a cadaver exhumed seven months after death, that unchanged, well preserved red corpuscles were still present, whereas of the white corpuscles only lymphocytes were to be seen, and these were somewhat changed in appearance. It appears, then, that the white corpuscles do not resist decay as well as the erythrocytes.

Loss of Vision from Methyl Alcohol Poisoning.—In view of the increasing number of cases of methyl alcohol poisoning, Bab recommends that, in case it does not seem feasible to prohibit the manufacture of wood alcohol, it might be given a disagreeable taste by the addition of small quantities of some harmless substance. This would perhaps be the best way to lessen the danger of its continued use as a beverage. He describes four cases demonstrating the pronounced degenerative processes from the action of the methyl alcohol.

Microsporia and Its Causative Agent.—Fischer describes an epidemic of microsporia in Berlin children. It affected mainly schools, orphan asylums, and public institutions. The causative agent in similar epidemics in the past had been *Microsporon audouini*, but in the present epidemic it seemed to be *Microsporon depauperatum*, a representative of the human type of the microsporon group that had been hitherto unknown in Germany. The clinical aspects of the disease were somewhat different from the usual picture of microsporia in man, in that the inflammation was more pronounced. An abscess developed in four of the 200 cases.

Proposed Reforms in Medical Teaching. J. Schwalbe.—p. 1220. Cont'n.

Acute Puerperal Inversion of the Uterus.—Von Jaschke reiterates that although partial or complete inversion of the uterus is one of the most dangerous complications associated with childbirth, yet prompt and proper treatment materially lessens the danger. Although mismanagement is generally responsible, partial inversions might possibly be caused by traction or relaxation of circumscribed portions of the uterus wall and contraction of adjoining portions. He thinks that in England and America too much weight is attached to local relaxation and unequal contraction. Zangemeister found on examination of the literature that in 98 per cent. of the cases traction played a part. Traction occurs almost always through the medium of the placenta, part or all of which has remained in the uterus. Occasionally, however, a submucous myoma may be a contributing factor. If relaxation of the uterine wall is pronounced, the placenta may exert traction by the force of its own weight, or a short cord may cause a partial inversion during expulsion of the

child. Inversion is favored without doubt by the fundal site and partial adherence of the placenta. Pressure on the relaxed uterus from above, as is applied in Credé's maneuver, produces the same effect as downward traction. No matter how the inversion may have been caused, therapy demands that puerperal inversion of the uterus be reduced at once. Von Jaschke admits, however, that Zangemeister and others oppose this view, maintaining that the shock of reduction, added to the shock caused by inversion, may prove serious. Even in the presence of severe hemorrhage, Zangemeister will not admit of immediate reposition, but endeavors to stop the hemorrhage by means of an elastic bandage fastened about the inverted organ. Von Jaschke cannot accept this teaching, and thinks that the bandaging causes a much greater shock than reduction under profound anesthesia. He regards the danger from infection as so great that its avoidance must be considered the main issue. However, if infection has already set in, he agrees with Zangemeister that the reduction of the inversion is contraindicated and that extirpation of the inverted organ, together with drainage of the Douglas pouch, must be done. But in fresh or recent cases infection is rare, and radical treatment should not be considered unless the inversion has existed at least six hours. He finds that profound anesthesia reduces to a minimum the shock manifestations sometimes occurring during reposition of the uterus. As a prophylactic measure or as a means of combating an already present shock, 2 c.c. of camphor and from 0.01 to 0.02 gm. of morphin will prove beneficial. The technic of the reposition is a delicate one. Brusk procedure is out of place. There should be no forcing of the organ through Bandl's ring, spasm of which can practically always be suppressed under profound anesthesia, aided by the effect of the morphin. Any remaining portions of the placenta may easily be, and should be, removed before the uterus is reverted. The manual technic follows: With the thumb, middle finger and index held in a cone shape, with the tips of the fingers he endeavors very gently to make an upward indentation at the lowest point of the inverted uterus. Sometimes it may be necessary to try another spot near by. When such a dent is produced, the pressure is slowly increased and the finger tips are gradually spread apart so as to cover a larger area. Care must be exercised, however, not to make the indentation broader than Bandl's ring. If this caution is not heeded, failure will result, and operators will be inclined to err and to ascribe their failure to a persistent spasm of Bandl's ring. However, after the indented portion has been carried past the cervical ring, the fingers may be spread out wider. The balance of the operation is usually easy. The still inverted portions are gradually drawn up by the upward rise of the fundus. If a high degree of atony persists, this will make reinversion more difficult. Pressure of the fingers must then be all the more even and steady. In such cases it will be found helpful, as soon as the reinverted portion has been brought up to Bandl's ring, to push gauze into the uterus, alongside of the operating hand. Then, as the reinversion proceeds, the gauze tampon is increased, which will check the hemorrhage, incite contraction and prevent a renewed spontaneous inversion of the uterus. Tamponade of the vagina with wide gauze, inserted in separate layers and tightly pressed together (the Kussmaul tamponade), will insure better results. Von Jaschke admits that there are a few cases in which it may be necessary to resort to instruments, but advises that the manual method be tried first.

Atypical Erythema Nodosum.—Within a few weeks of each other, five young women, whose ages ranged from 16 to 22, presented themselves at the University Clinic in Greifswald with similar skin lesions. Denecke states that on the front and outer side of the lower third of the legs there were red and reddish blue spots just above the ankle. The skin was smooth and shiny. A handbreadth area was swollen. Suction caused the redness to disappear and leave a pale ground. The spots were irregular, clearly circumscribed, and presented a mottled appearance. The skin was firmly attached to the substratum and felt hard. Finger pressure was slightly painful and left no indentation. In fact, it was

difficult to make any impression on the skin. The skin when compressed into folds showed a very fine wrinkling. All five patients presented heart symptoms pointing to a pathologic condition of the endocardium, and all had rheumatic pains in the ankles and some in other joints. The differential diagnosis of the condition presented some difficulty. Denecke mentions half a dozen dermatoses that were considered and excluded before repeated palpation of the affected area led him to his final diagnosis of chronic, recurring erythema nodosum. The differentiation from erythema exudativum multiforme was not so difficult because the appearance of the dermatosis did not rapidly change from day to day; there were no outlying lesions, no patches with elevated edges, no tubercles, no blisters, no scales nor crusts. Sodium salicylate, 5 gm. daily, was the principal therapeutic agent. He comments on the coincidence of five cases, all in girls, and all localized in the same region, the area on the leg between the skirt and the shoe, which is most exposed to wind and weather, and the fact that all were in domestic service, obliged to be much on their feet.

Treatment of Old Ulcerating Wounds.—Wounds with extensive loss of tissue may refuse to heal, or, healing partially, they break down again and ulcerate. Dürig had found healing of such wounds difficult, and, after fruitless attempts to heal them, it became necessary to cover them with a transplant. The cause of the condition no doubt is that the central portions of the wound are not adequately supplied with blood. The scar tissue becomes more fibrous. The blood vessels grow smaller. The scar is deprived of fluid. It shrinks and is put on the stretch. The color changes from red to white, and finally in its center an ulcerous condition is set up. The indications are for an improvement in the blood supply. It occurred to Dürig that a procedure used years ago for the treatment of phagedenic ulcer would be helpful in treating ulcerating scar wounds, namely, lavage with a hot solution of potassium permanganate. Dürig uses for this purpose an irrigation apparatus at an elevation of 2 meters. The port wine red solution of potassium permanganate has a temperature of 40 C. The glass end-piece is fused, leaving only a pinhead opening, so that the wound may be sprayed with a fine, cutting stream. Two liters of the solution are needed for a ten minute lavage, which is done daily. After the lavage a dry dressing is applied. The viscous coating of the wound is often replaced in a few days by healthy granulations, and epithelization, beginning with the edge of the wound, soon covers the whole surface. Even though, because of the extent of the wound, a transplant should be necessary, Dürig finds this preliminary lavage treatment beneficial, as the wound is well cleansed and its size materially reduced.

Effect of Epinephrin on Blood Pressure.—Bauer has found that occasionally the subcutaneous administration of epinephrin in man causes a primary and not inconsiderable lowering of blood pressure that is not soon followed by a rise of pressure.

- Therapy of Malignant Edema and Sepsis. W. Hancken.—p. 1268.

Orogenous Pyemia and Sepsis.—The pyemic and septic forms of orogenous infectious disease may sometimes be differentiated, although frequently, Heine states, they overlap. Remittent and intermittent fever (with or without chills) and metastases characterize the pyemic form. For the septic form, continuous fever, signs of poisoning (prostration, mental disturbance, delirium) and a stormy course are significant. In the septic form we may assume the

presence of increasing numbers of pyogenic bacteria in the blood (bacteremia) resulting in a poisoning of the organism by their toxins; or there may be a pure toxemia. This toxemia does not necessarily have its sole starting point in the original focus, as in diphtheria. Kümmel has shown that in other organs of the body (brain, kidneys) secondary bacterial foci may have formed, which maintain the supply of toxins. Heine admits that, exceptionally, this general infection may occur without involvement of the transverse or lateral sinus, but states that such cases are so rare that they may be safely left out of account, so far as indications for operative intervention are concerned. In one case he felt compelled to assume that the source of the pyemic fever was the suppuration in the mastoid process itself. He finds that most frequently the inflammatory process is conveyed to the sinus wall through contact with adjoining diseased bone. In some cases there is disintegration of bone tissue, and granulations form and shoot up along the sinus wall, resulting in an extradural abscess or suppuration around the sinus. He agrees with Haymann that mere inflammation of the sinus wall does not cause a thrombus in the sinus, and, with Lubarsch, that changes in the blood and retardation of the blood stream through the affected area are necessary accessory factors. The formation of a thrombus is gradual, and it arises ordinarily from a parietal coagulum. An obstructive thrombus is seldom formed at the start. Heine describes his mode of treatment in detail, but warns that every case must be considered on its own merits, and treated accordingly; for if one were to follow any single plan of treatment in all cases, more harm than good would often be done.

Nerve Shifting and Joint Adjustment in Relation to Primary Nerve Suturing.—The adjustment of joints so as to make a "cut-off" and save distance for nerve trunks, Bran-

N, normal position of nerve; V, position of nerve after shifting.

des and Meyer remark, has been done for some time, but the shifting of the position of nerves (nervenverlagerung) in order to accomplish a similar purpose dates back to Wrede, who in 1916 published in the *Zentralblatt für Chirurgie* his article on "Nervenverlagerung zur Erzwungung einer direkten Nervennaht." The authors give an enthusiastic account of what Wrede has accomplished by his nerve shifting procedure. For example, in a 10.5 cm. defect of the median nerve the most that could be gained by adjustment of the elbow and wrist joints was 5 cm.; but, when the proximal nerve stump was removed from its bed in the pronator teres muscle and was embedded on this muscle and the bicipital fascia, as shown in the accompanying illustration, 5 cm. more were gained, so that the nerve could be sutured without any tension whatever. The authors, aroused by Wrede's success to make further research, have made extensive investigations on the cadaver and here publish their results. They have determined the maximal defects that various nerves may have and still permit the stumps to be brought together for primary suturing by means of joint adjustment and

nerve shifting. They also give details as to how various joints should be adjusted in order to provide for shortening the course of different nerve trunks.

Therapie der Gegenwart, Berlin

Treatment of Tuberculosis with Living Turtle Tubercle Bacilli. F. Baum.—p. 398.

Dilatation of the Heart with Thyroid Insufficiency.—Zondek warns that dilatation of the heart with hypothyroidism is of common occurrence, and it does not yield to digitalis. Neither the size of the heart nor the diuresis, nor the tendency to cyanosis, shows any modification under the usual heart tonics, but a prompt change for the better is apparent when the deficit in thyroid secretion is made up by thyroid treatment. All the subjective and objective pathologic findings retrogress, he says, and in two months the outline of the heart usually has returned to normal, even when the dilatation had been extreme. The heart disturbances with thyroid insufficiency are characterized by sluggish action and by the relative insignificance of the disturbances in comparison with the degree of dilatation. Electrocardiography serves as a useful guide when to suspend the treatment. When the high thyroid peak has dropped back to normal, the treatment can be resumed.

An Artificial Esophagus.—Hirschmann reports that the outcome in his three cases was so excellent that he does not hesitate to commend his technic for the systematic relief of absolutely impermeable stenosis of the esophagus. One young woman is in the best of health now, a year and a half after the operation. The various steps are illustrated. A short loop of the jejunum is moved to a bed under the skin of the chest, and one end is implanted in the stomach. Then the skin is incised to the right and left of the median line, these parallel incisions 6 or 7 cm. apart. The inner lips of the two incisions are turned back and sutured together, thus forming a skin-lined tunnel from throat to stomach. The stump of the esophagus is brought out through the skin in the neck, and sutured to the upper end of the skin-lined tunnel. Then the lower end of the latter is sutured to the short segment of the bowel loop that has been brought up to bridge the gap between the skin tunnel and the stomach. In all the steps of the operation he is careful to leave sufficient blood supply for all parts concerned.

*Nearthrosis. A. Bier.—p. 2.

*Means to Facilitate Thyroidectomy. M. Claessen.—p. 9.

Extraperitoneal Laparotomy for Kidney Tumors. J. J. Stutzin.—p. 10.

Nearthrosis.—Bier tries to facilitate the formation of the new bursa in the new joint by injecting gelatin or sodium chlorid solution or inducing accumulation of serum in the joint cavity or leaving the extravasated blood. He gives case reports with each of these methods. None of the methods gives constantly good results, and infection is liable with each of them. In two cases the making of the new joint was followed by fatal infection; in one with an interposed flap of fascia, 250 c.c. of salt solution had been injected. The danger of infection is particularly great when the knee is flexed. He now fills the cavity after the resection with 5 per cent. tincture of iodine, and cleans it out again after a time and then sutures. He has thus treated fourteen joints, including twelve in which the ankylosis resulted from a suppurative process. The iodine induces an acute irritation which thus disinfects the cavity by the natural, biologic means. All healed by primary intention. The after-treatment is more difficult than the operation. He has found that the muscles may promptly recuperate function when they have long been useless on account of ankylosis. In one case the quadriceps rapidly recuperated after twenty years of

disuse from ankylosis due to a tuberculous process in the knee. The extensors are much more apt to atrophy than the flexors. He is convinced further that nervous and toxic influences may be responsible for the atrophy of muscles, more than any other factors. Active exercise is the best means to strengthen a weakened muscle. He only exceptionally applied force to mobilize a joint, but this is often very useful in correcting a nearthrosis that has developed ankylosis.

Thyroidectomy.—Claessen advises passing stout silk around behind the thyroid to lift it up with. He does not pass the silk through the thyroid tissue as this might entail hemorrhage. When these threads are to be left behind, as with partial thyroidectomy, he uses catgut instead of silk. Another use for these catgut encircling slings is to tie off and thus obliterate in time the remaining portion of the thyroid after partial removal. A series of catgut threads were thus tied around the stump, and it harmlessly shriveled up under them in one case described.

Treatment of Gonorrhea in the Female. H. Brauns.—p. 16.

Prophylaxis of Thrombosis.—Fehling declares that we are not so powerless as formerly supposed against thrombosis and embolism. Getting the patients up early after childbirth and operations is a great advance, and systematic exercising is also of great aid in prevention. Even more important is the systematic strengthening of the heart with tonics before and immediately afterward, and he cites figures showing the great improvement in his service since this has been done. He introduced this heart treatment in 1910. Before that he had had thrombosis in 5 per cent. and embolism in 1.25 per cent. in his myomectomy cases; 7.5 and 5.5 per cent., respectively, in his cancer cases, and 4 and 0.7 per cent. in his operations on the adnexa. The corresponding figures since 1910 have been 3.1 per cent. thrombosis and 0 embolism; 2.1 thrombosis and 1 embolism, and 1.4 per cent. thrombosis and 0.5 per cent. embolism. Other prophylactic measures are the bandaging of varicose veins before an operation. This prevents their becoming aggravated. Massage might aid in curing them, or compressed air massage, or obliteration of the varicose veins in the leg by injection of 1 or 2 c.c. of a 1 per cent. solution of mercuric chlorid with equal parts of a 1 per cent. sodium chlorid solution, injected into the vein, avoiding the most dilated portion and repeating as indicated. The patient can go about his business as usual, reclining only when there is a sensation of oppression. Zirn and Linser reported in 1919 that this procedure had been successfully applied in 800 cases without harm. Even with already developed ascending thrombosis, ligation of the vein and excision of the segment might be tried. Although embolism in the saphena is rare, yet this justifies the procedure. Haward has suggested intravenous injection of a 0.5 per cent. solution of citric acid to reduce the tendency to coagulation. Chantemesse for the same purpose has given 15 or 18 gm. citric acid in the course of two or three days before myomectomy. Fehling says that if this does not injure the stomach it seems promising. Riemann and Wolf recommend injection of 1 gm. herudin repeated in four hours, Kuhn injects sugar solution by the vein: experiments on rabbits seem to promise success with this. His formula is 4 gm. dextrose; 0.04 gm. sodium saccharate; 0.85 sodium chlorid and 100 c.c. distilled water, injecting 1 or 2 gm. by the vein. If there is already thrombosis before the laparotomy, or if the subject has previously had embolism, Fehling advises that some of these measures might be tried.

Dangers of Blood Transfusion in Obstetrics.—Opitz has had unfavorable experiences with reinfusion of the blood taken from the abdominal cavity after tubal abortion. In future he will simply leave the blood in the abdominal cavity unmolested. No harm from this was ever observed in the

numerous cases in which this was done in Olshausen's service. The blood seemed to be always rapidly resorbed. The disturbances from autolysis of the blood are fewer and less than those with reinfusion of the blood after it has been cleared out. In two cases in which citrated blood from another person was transfused, serious disturbances followed, fatal in one instance. It was afterwards found that the donor's blood had a strong agglutinating action on the other blood.

To Shut Off the Blood from the Lower Half of the Body.

—THE JOURNAL described at the time Momburg's method of hemostasis by constricting the body at the waist line, winding a rubber tube around the abdomen. Sehrt describes here a contrivance which accomplishes this in a more scientific manner by pressure on the abdominal aorta alone. The instrument is something like a pair of compasses. It encircles the abdomen, and a square jog in one branch fits down over the aorta and presses it back against the spine, flattening it out and closing the lumen. The compression is regulated and maintained with a thumbscrew, and it can thus be very gently and gradually applied and removed, and the resulting ischemia is complete. The device can be applied with the left hand and without moving the patient, the straight branch being easily slipped under the back. The instrument is light and takes up very little space in the physician's bag, and the testimony on all sides is said to be favorable.

Gauss endorses the advantages of a device of the kind, and states that the resulting ischemia has always caused strong contractions in the uterus in his clinical experience with an instrument he devised for the purpose some years ago, with a pad device. He adds that Sehrt's instrument is much lighter and simpler, and deserves the preference if it fulfils its promise. He even advises its prophylactic use when there is reason to anticipate too much hemorrhage, and he has successfully applied it in eleven cases as he describes. He queries whether it might not be applied as a routine measure to ward off the natural loss of blood at childbirth.

*Influenzal Empyema. Auna Sabroe.—p. 63.

*Case of Lethargic Encephalitis. G. R. Ulrich.—p. 71.

Empyema.—Sabroe relates that 94 cases of empyema as a sequel of influenza were treated at the public hospital, with 17 deaths, but the general infection rather than the empyema was responsible for all but 7 of the fatalities. Operative treatment was necessary in 90 of the cases, aspirating and draining, requiring from thirty to 169 days of hospital care, with an average of sixty-seven days. The influenzal empyema was capricious in its course, and required constant oversight, the temperature running up at times, but the general condition kept surprisingly good throughout as a rule.

Lethargic Encephalitis.—Ulrich calls attention to the stormy onset and brief course of the disease in the young man and the total lack of paresis of any kind. Total unconsciousness and convulsions seemed to be the only manifestations of the disease, and recovery was complete in less than two weeks with no memory of the twelve days of the sickness.

ACIDOSIS IN NEPHRITIS*

ARTHUR F. CHACE, M.D.

AND

VICTOR C. MYERS, Ph.D.

NEW YORK

The subject of acidosis in nephritis is one of such practical importance that it deserves emphasis from a clinical standpoint. Many significant observations bearing on this general topic have accumulated during the last ten years. In the study of this question, Van Slyke's simple method¹ of determining the alkali reserve of the body with the aid of the carbon dioxide combining power of the blood has been of great assistance. We have utilized this method to excellent advantage since Van Slyke's preliminary publication² in 1915.

The term acidosis, although originally coined by Naunyn to apply to the ketosis of diabetes, has come to be used in a much broader sense with the development of our knowledge of this subject. Obviously, acidosis may result either from an abnormal formation of acid substances or, as in nephritis, from a decreased elimination of normally formed substances. Under conditions of health, the blood is uniformly maintained at a constant slightly alkaline reaction through the influence of the bicarbonate, phosphate and proteins of the blood.

The carbonates of the blood have been called by L. J. Henderson the first line of defense. Increased pulmonary ventilation, as occurs with dyspnea or hyperpnea, serves to increase the excretion of carbon dioxide, thus keeping the reaction of the blood within normal limits. In conditions of acidosis, other acids may combine with the bicarbonate, robbing the body of its alkali reserve. Under ordinary conditions, however, the kidneys are able to secrete an acid urine from a nearly neutral blood through the medium of acid phosphate, constituting a second means of defense. From the investigations of Marriott and Howland³ it appears that it is just this factor which breaks down in the acidosis of nephritis. They have found the inorganic phosphates of the blood serum increased to many times the normal in nephritic acidosis, although nephritic cases without acidosis did not show this change. Other means of defense against acidosis are

the blood and body proteins, which are able to take up considerable amounts of acids without marked change in reaction, and the ability to form alkali, i. e., ammonia. The latter factor is of considerable importance in the acidosis of such conditions as diabetes and pernicious vomiting, but apparently of little significance in nephritis.⁴

DETERMINATION OF DEGREE OF ACIDOSIS

A number of different criteria have been suggested as a measure of the degree of acidosis: (1) lowered carbon dioxide combining power of the blood; (2) lowered alveolar carbon dioxide tension; (3) decreased affinity of hemoglobin for oxygen; (4) reduced alkalinity of the blood; (5) increased hydrogen ion concentration of the blood; (6) increased intensity of urinary acidity (hydrogen ion concentration), and (7) the retention of alkali by the body in cases in which the kidney is capable of rapidly excreting an excess of alkali.

All of these have furnished valuable information in the development of our knowledge of this subject, but the first, second and seventh have yielded information of special clinical value. Although the carbon dioxide tension of the alveolar air may readily be ascertained at the bedside with Marriott's simple apparatus,⁵ the information is not as reliable as the carbon dioxide combining power of the blood determined by the Van Slyke method. Nevertheless, the method of Marriott may be of great clinical assistance. That the bicarbonate depletion may roughly be determined by administration of sodium bicarbonate has been pointed out by Sellards,⁶ and by Palmer and Henderson,⁷ and this method has been in practical use for several years. Normally from 5 to 10 gm. of sodium bicarbonate are sufficient to change the reaction of the urine, but in the acidosis of advanced nephritis the deficiency may amount in exceptional instances to as much as 100 gm. of bicarbonate or more.

Palmer and Van Slyke⁸ have recently studied this question rather carefully in connection with the carbon dioxide combining power of the blood. They found that in most pathologic cases the urine did not become more alkaline than blood until a higher plasma bicarbonate had been reached than in normal individuals. This would result in the giving of unnecessary and

possibly injurious amounts of bicarbonate, if the administration was continued until the urine turned alkaline, as has been the usual clinical procedure. The bicarbonate retention may therefore indicate a much more severe acidosis than actually exists. Palmer and Van Slyke advise carefully controlling the therapeutic use of sodium bicarbonate. They have calculated that taking 42 pounds as the unit of weight, 0.5 gm. of sodium bicarbonate will raise the plasma carbon dioxid

1 per cent. by volume. In view of this, it is possible to calculate the amount of alkali required to restore the plasma bicarbonate to normal.

The normal range for the carbon dioxid combining power of the blood in the adult, as shown by Van Slyke, Stillman and Cullen,⁹ is from 55 to 75 c.c. of carbon dioxid per hundred c.c. of plasma.

OBSERVATIONS ON ACIDOSIS IN NEPHRITIS

In Table 1 are given observations in twenty fatal cases of nephritis with marked nitrogen retention. These cases were the first twenty in a series of 100 having high figures for the blood creatinin¹⁰ in which observations of the plasma carbon dioxid had been obtained. It will be noted that without exception these cases show a pronounced acidosis, and in two instances, Cases 1 and 11 (compare also Table 2), this was sufficient to have been the immediate cause of death. Only in one case was the carbon dioxid found to be above 40, and here alkali had been given the day previous.

To emphasize the importance of acidosis in nephritis, three groups of two cases each are tabulated in Table 2. It is not believed that detailed case histories would aid especially in any deductions that might be drawn, and

they are therefore omitted. The first two patients suffered from severe chronic interstitial nephritis, showing marked nitrogen retention and acidosis. It is worthy of note that E. M. was up and about at the time of the first analyses, while A. N., after a short stay in the hospital, was at home for a period of seven weeks feeling improved. In both of these cases there was pronounced acidosis, and at the end the carbon dioxid dropped to such a low level as to be incompatible with life. The observations of Whitney¹¹ make it evident that such low figures may be the direct cause of death. As these patients did not receive alkali (until after the last recorded test), the carbon dioxid obviously fell to a lower level than would otherwise have been the case.

W. W. and J. McC. represent cases of chronic nephritis admitted to the hospital with pronounced symptoms of acidosis. Although both patients died about one month after leaving the hospital, they showed considerable clinical improvement, this being coincident with the rise in the carbon dioxid combining power of the blood.

The last two patients, M. McA. and W. C., men of 44 and 49 years, respectively, were cases of acute nephritis showing pronounced acidosis (very marked dyspnea), but ending in complete recovery. Although this type of case is apparently not frequently encountered, it furnishes an interesting contrast to the preceding two groups. W. C. was admitted supposedly in

"uremic" coma. On estimating the creatinin and urea in the blood, however, we were surprised at the comparatively slight nitrogen retention, but an examination of the carbon dioxid combining power disclosed the apparent difficulty. Two infusions of sodium bicarbonate, 12 gm. each, on the fifteenth and sixteenth, produced quite remarkable clinical results, and in less than two weeks the blood findings were normal.

10. Myers, V. C., and Killian, J. A.: Am. J. M. Sc. **157**: 674 (May) 1919.

11. Whitney, J. L.: Studies on Acidosis; The Immediate Cause of Death, and Remarks on the Acidosis of Nephritis, Arch. Int. Med. **20**: 931 (Dec.) 1917.

Several years ago, Peabody¹² stated that the development of acidosis bears little relation to the accumulation of nonprotein nitrogen in the blood or to the phenolsulphonephthalein output, although he pointed out that in the terminal stages of uremia there may be a high grade acidosis. Our experience likewise leads us to believe that there are many cases of nephritis with considerable nitrogen retention that show little acidosis; but this certainly is not true of the more advanced cases. From the data reported in Table 1, it would appear that all fatal cases of chronic nephritis with marked nitrogen retention show a severe acidosis, sufficient in some instances to be the actual cause of death.

What part acidosis plays in the clinical symptoms of so-called uremia is difficult to answer. Patients with pronounced acidosis present a somewhat different clinical picture; but until we possess additional information regarding the cause of uremic symptoms, whether they are due to a toxic base such as methylguanidin, to a deficiency in calcium, or to something else, it will not be possible to clear up this problem satisfactorily. Palmer and Henderson, Sellards, Peabody and Whitney, in the papers previously referred to, have given illuminating discussions of the acidosis problem in nephritis. So far as the acidosis goes, it is now possible to obtain very reliable information from the carbon dioxid combining power of the blood plasma with the relatively simple Van Slyke method; and furthermore, the administration of alkali can be particularly well controlled with this method. Acidosis is a fairly prominent feature of many cases of acute nephritis, and is present in severe form in all terminal cases with marked nitrogen retention.

CONCLUSIONS

All fatal cases of chronic nephritis with marked nitrogen retention show a severe acidosis, sufficient in many instances to be the actual cause of death.

In some cases of acute nephritis and acute exacerbation of chronic nephritis the distress is apparently due to the acidosis, since the judicious use of sodium bicarbonate results in general clinical improvement. With the rise in the carbon dioxid combining power of the blood, the dyspnea and hyperpnea disappear.

Child Surveys.—The need for surveys to reveal exactly what a child ought to have in order to be properly reared and what his chances are for getting it under present conditions is one of the topics emphasized in the seventh annual report of the chief of the Children's Bureau of the U. S. Department of Labor. Special investigations made by the Children's Bureau in three American cities show how babies have suffered as a result of the advance in the price of milk. In Baltimore, of 728 children between 2 and 7 years of age, only 29 per cent. are now having fresh milk to drink, as against 60 per cent. a year ago; in Washington, half of those between 2 and 7 years visited by the public health nurses were receiving no fresh milk to drink; and in New Orleans conditions were even worse. Studies of the type recommended by the chief of the Children's Bureau would seek to determine all a child's needs. They would be based on actual living conditions in various types of communities; and would accordingly have a practical and not merely a theoretical value. Through them mothers would obtain an authoritative statement concerning the basic needs of growing children, and communities would be given an insight into the way in which those needs may be met.

HEMOLYTIC ACTIVITY OF SOLUTIONS OF ARSPHENAMIN AND NEO-ARSPHENAMIN *

JOHN A. KOLMER, M.D.

AND

ELIZABETH M. YAGLE, B.S.

PHILADELPHIA

In the preparation of solutions of arspenamin and neo-arsphenamin for administration by intravenous injection, sterile freshly distilled water or saline solutions (generally 0.4 per cent. sodium chlorid in distilled water) are commonly employed as solvents; the solution of arspenamin so prepared is acid and highly toxic and requires neutralization with an alkali before administration, 15 per cent. solution of sodium hydroxid being commonly used for this purpose. On the addition of sodium hydroxid, the solution becomes very turbid, owing to the precipitation of the insoluble base of arspenamin; with the further addition of alkali, the solution is neutralized and "clears," with the formation of the soluble monosodium salt. The addition of still more alkali to this clear solution (usually one third of the amount required for neutralization and clearing) results in the hydrogen atoms of both hydroxyls becoming replaced with sodium, and the production of a disodium salt of arspenamin. Ehrlich originally advised the administration of the monosodium salt (solutions neutralized with sodium hydroxid just to the point of neutralization and clearing), but recently the tendency has been to add a little excess of alkali with the production or partial production of the disodium salt, which has been regarded as somewhat less toxic. Solutions of neo-arsphenamin, being neutral, do not require the addition of alkali.

While the causes and nature of the reactions following the intravenous injection of arspenamin and neo-arsphenamin are not as yet definitely known, one of us (Kolmer) with Schamberg, Raiziss and Weiss¹ has recently shown that solutions of arspenamin in water possess hemolytic properties, and that this factor may exert some influence in the pathogenesis of the untoward symptoms following intravenous injections of arspenamin. Solutions of neo-arsphenamin were reported as being practically devoid of hemolytic properties.

HEMOLYTIC ACTIVITY OF ARSPHENAMIN

The hemolytic activity of solutions of arspenamin in water may be ascribed to three factors, namely, (1) the direct hemolytic activity of arspenamin; (2) the hemolytic activity of nonisotonic solvents (water or hypotonic saline solutions), and (3) the hemolytic activity of sodium hydroxid, especially when used in excess for the production of the disodium salt.

When arspenamin is dissolved in water and the solution is neutralized with sodium hydroxid, some sodium chlorid is produced but never enough to render the solution isotonic; 0.1 gm. of arspenamin dissolved in water and neutralized with sufficient sodium hydroxid to produce the monosodium or disodium salt yields about 0.0247 gm. of sodium chlorid. *For the*

preparation of isotonic solutions, varying strengths of sodium chlorid in distilled water must be used according to the total volume of fluid desired; a salt solution of one uniform strength does not suffice for all concentrations, as thus indicated:

0.1 gm. in 50 c.c. isotonic solution requires the use of 0.82 per cent. sodium chlorid solution (0.6 gm. in 300 c.c.).
0.1 gm. in 40 c.c. isotonic solution requires the use of 0.81 per cent. sodium chlorid solution (0.6 gm. in 240 c.c.).
0.1 gm. in 30 c.c. isotonic solution requires the use of 0.79 per cent. sodium chlorid solution (0.6 gm. in 180 c.c.).
0.1 gm. in 20 c.c. isotonic solution requires the use of 0.77 per cent. sodium chlorid solution (0.6 gm. in 120 c.c.).
0.1 gm. in 10 c.c. isotonic solution requires the use of 0.68 per cent. sodium chlorid solution (0.6 gm. in 60 c.c.).
0.1 gm. in 5 c.c. isotonic solution requires the use of 0.47 per cent. sodium chlorid solution (0.6 gm. in 30 c.c.).
0.1 gm. in 4 c.c. isotonic solution requires the use of 0.33 per cent. sodium chlorid solution (0.6 gm. in 24 c.c.).

Since salt solutions varying from 0.8 to 0.9 per cent. may be regarded as isotonic for practical purposes, the standard physiologic sodium chlorid solution (0.85 per cent.) may be used when each 0.1 gm. of arspenamin is dissolved in 30 c.c. or more of saline solution (equivalent to 0.6 gm. dissolved in 180 c.c. or more); possibly the same solution could be used when each 0.1 gm. is dissolved in 20 c.c. (equivalent to 120 c.c. for 0.6 gm.), which is generally recommended; but when more concentrated solutions are employed, the strength of the saline solution varies accordingly and becomes increasingly important, since concentrated solutions of arspenamin are more hemolytic than dilute solutions.

The results of experiments shown in Table 1 were observed by preparing solutions of the acid (non-neutralized) and of the monosodium (alkali added just to neutralization and clearing) and disodium (one third excess alkali) salts of arspenamin in water and isotonic saline solutions in seven concentrations varying from 0.1 gm. in 50 c.c. (equivalent to 0.6 gm. in 300 c.c.) to 0.1 gm. in 4 c.c. (equivalent to 0.6 gm. in 24 c.c.); each of the resulting forty-two solutions was

exactly the same manner, employing defibrinated rabbit blood and rabbit blood collected with sodium fluorid to prevent coagulation, in order to test the hemolytic properties of the solutions under conditions more closely approaching those in vivo and in the presence of plasma or serum.

The results of the four sets of experiments were closely parallel and may be thus summarized:

1. Acid or non-neutralized solutions and solutions of the monosodium and disodium salts of arspenamin

0.1 gm. in 4 c.c. (0.6 in 24 c.c.)	0.8	0.2	3.0	0.2	3.0	1.0

* This table gives the largest amounts of a 50 per cent. suspension of washed erythrocytes completely hemolyzed by 1 c.c. of each solution of arspenamin after the mixtures had been incubated at 38 C. for one hour and stood in a refrigerator over night.

† Water alone (1 c.c.) caused the complete hemolysis of 0.6 c.c. of cells.

in isotonic saline solution were decidedly less hemolytic than corresponding solutions in plain distilled water. Even in isotonic saline all solutions of arspenamin showed some hemolysis, owing to the direct hemolytic activity of the drug itself, as previously mentioned. As shown in Tables 1 and 2, while 1 c.c. of a solution of arspenamin in water in the proportion of 0.6 gm. in 120 c.c. caused the complete hemolysis of from 0.6 to 1.0 c.c. of 50 per cent. suspensions of human and sheep erythrocytes, similar solutions in isotonic saline solution hemolyzed only from 0.1 to 0.2 c.c. of the same cells, these and similar results with defibrinated and fluorided rabbit blood indicating that solutions of arspenamin in isotonic saline solutions are generally from three to ten times less hemolytic than similar solutions in plain distilled water.

2. Concentrated solutions of arspenamin in water and isotonic saline are more hemolytic than dilute solutions; this is to be expected, owing to the direct hemolytic activity of arspenamin, which effects are naturally most marked in concentrated solutions. For example, while 1 c.c. of a solution of the disodium salt in isotonic saline in proportion of 0.6 gm. of arspenamin in 300 c.c. failed to produce complete hemolysis of 0.1 c.c. of 50 per cent. suspensions of human and sheep erythrocytes, concentrated solutions, as 0.6 gm. in 24 c.c. of isotonic saline, produced complete hemolysis of from 0.6 to 1.0 c.c. of cells, indicating that the latter solution was from six to ten times more hemolytic than the dilute solution. This gradual increase in hemolytic activity of concentrated solutions is shown in Tables 1 and 2, and similar results were observed with defibrinated and fluorided rabbit blood.

3. Solutions of the monosodium salt of arspenamin in water and saline are more hemolytic than acid solutions, and solutions of the disodium salt are more hemolytic than those of the monosodium salt. We have ascribed these differences to the well known and marked hemolytic activity of sodium hydroxid and alkalis in general. Of most practical significance are

TABLE 1.—THE HEMOLYTIC ACTIVITY OF ARSPHENAMIN IN VARYING SOLUTIONS FOR HUMAN ERYTHROCYTES*

0.1 gm. in 4 c.c. (0.6 in 24 c.c.)	0.2	0.1	0.8	0.2	1.0	0.6

* This table gives the largest amounts of a 50 per cent. suspension of washed erythrocytes completely hemolyzed by 1 c.c. of each solution of arspenamin after the mixtures had been incubated at 38 C. for one hour and stood in a refrigerator over night.

† Water alone in 1 c.c. caused the complete hemolysis of 0.2 c.c. of cells.

tested for hemolytic activity by placing 1 c.c. in eight test tubes and adding increasing amounts of a 50 per cent. suspension of washed human erythrocytes, thus: 0.1, 0.2, 0.4, 0.6, 0.8, 1.0, 2.0 and 3.0 c.c. These mixtures and controls were placed in a water bath at 38 C. for one hour and then in a refrigerator over night, the occurrence and degree of hemolysis being recorded the following day.

In Table 2 are shown the results of duplicate experiments conducted at the same time with sheep erythrocytes. Additional experiments were conducted in

the relative hemolytic activities of solutions of the monosodium and disodium salts; for example, 1 c.c. of a solution of the monosodium salt of arspfenamin in isotonic saline solution in the proportion of 0.6 gm. in 120 c.c. produced complete hemolysis of less than 0.1 c.c. of human and sheep corpuscles, whereas similar solutions of the disodium salt caused complete hemolysis of 0.2 c.c. of the same cells. These and similar examples with rabbit blood indicate that solutions of the disodium salt of arspfenamin are from two to eight times more hemolytic than corresponding solutions of the monosodium salt. We may repeat in this connection that solutions of the monosodium salt are designated as those to which just sufficient sodium hydroxid had been added to neutralize and "clear" the solution; solutions of the disodium salt contained this amount of alkali plus one third excess. Whether the monosodium and disodium salts of arspfenamin are more hemolytic than the base has not been determined; we have ascribed the results to the alkali, the solutions of the disodium salt being more hemolytic in proportion to the larger amounts of alkali added to the solutions.

HEMOLYTIC ACTIVITY OF NEO-ARSPHENAMIN

Neo-arsphenamin, in contrast to arspfenamin, is not hemolytic; but *dilute solutions of neo-arsphenamin*

TABLE 3.—THE HEMOLYTIC ACTIVITY OF NEO-ARSPHENAMIN IN WATER AND PHYSIOLOGIC SODIUM CHLORID SOLUTION FOR HUMAN ERYTHROCYTES

0.1 gm. in 2 c.c. (0.9 in 18 c.c.).....	No hemolysis	No hemolysis
0.1 gm. in 1 c.c. (0.9 in 9 c.c.).....	No hemolysis	No hemolysis

* Water alone (1 c.c.) caused the complete hemolysis of 0.4 c.c. of a 10 per cent. suspension of corpuscles.

† The largest amount of a 10 per cent. suspension of washed human erythrocytes in physiologic sodium chlorid solution completely hemolyzed after incubation at 38 C. for one hour and stood over night in a refrigerator.

in sterile distilled water are hemolytic, whereas concentrated solutions are not; both dilute and concentrated solutions in physiologic sodium chlorid solution (0.85 per cent. sodium chlorid in distilled water) are without demonstrable hemolytic properties.

The results of experiments conducted as described above, except that washed human corpuscles in 10 per cent. suspension were employed, are shown in Table 3. Duplicate tests were conducted with defibrinated and fluorided rabbit blood.

When neo-arsphenamin is dissolved in water, some inorganic matter is produced, including sodium chlorid. The exact amount of sodium chlorid produced by a given amount of the drug remains to be determined; but it would appear, according to our results, that when 0.9 gm. of neo-arsphenamin is dissolved in 27 c.c. of water, enough salt is furnished to render the solution isotonic. This indicates that in 3 per cent. solutions of neo-arsphenamin there is produced somewhere in the neighborhood of 0.7 per cent. inorganic salts responsible for isotonicity or, in other words, the solution of 0.9 gm. of neo-

arsphenamin in about 30 c.c. of water produces about 0.2 gm. of these salts sufficient for rendering the water isotonic. As shown in Table 3, dilute solutions of neo-arsphenamin (0.9 gm. in 90 c.c. or more of water) are decidedly hemolytic because the inorganic salts are too highly diluted with water; solutions of 0.9 gm. in from 36 to 50 c.c. are slightly hemolytic, while solutions of 0.9 gm. in 30 c.c. or less of water are nonhemolytic. These results would have been more striking if 50 per cent. suspensions of corpuscles had been used, because a 10 per cent. suspension in saline solution, as employed in these experiments, carried over more isotonic sodium chlorid solution than a 50 per cent. suspension of cells.

As shown in Table 3, all solutions of neo-arsphenamin in physiologic sodium chlorid solution were nonhemolytic; unquestionably, all solutions, and particularly the concentrated solutions, were hypertonic by reason of the addition of the sodium chlorid liberated by the solution of the drug, but none of the solutions produced hemolysis.

PRACTICAL SIGNIFICANCE

The practical significance of these results depends almost entirely on the importance of intravascular hemolysis following the intravenous administration of arspfenamin and neo-arsphenamin; if hemolysis is held responsible for some of the untoward effects following the administration of these drugs, the results are of considerable practical importance and clearly indicate the adoption of certain steps in the technic of administration calculated to reduce the degree of hemolysis. Animal tests consisting of the intravenous injection of rats with 2 per cent. solutions of the disodium salt of arspfenamin in water and in isotonic saline have not shown constant differences in toxicity; similar tests employing 4 per cent. solutions of neo-arsphenamin in water and physiologic sodium chlorid solution have yielded closely similar results so far as life or death of the experimental animals were concerned. Possibly these tests are not sufficiently delicate for eliciting the effects ascribable to hemolysis alone; abundant clinical experience has shown that solutions of arspfenamin in water are well borne, and some physicians believe that the solution of the disodium salt of arspfenamin is better borne than that of the less hemolytic solution of the monosodium salt. However, comparative studies may show differences and a decrease of reactions in favor of the use of the less hemolytic solutions; we are not aware of such studies having been made on a sufficiently large scale to be conclusive, but suggest the advisability of conducting the investigation by reason of the very important practical value of the subject.

TECHNIC FOR REDUCING HEMOLYTIC ACTIVITY

While hemolysis in vivo may be insufficient to produce appreciable harm, it would appear quite certain not to do good, and it is advisable to reduce as much as possible the hemolytic activity of solutions of arspfenamin and neo-arsphenamin; these objects may be obtained by observing the following points in technic:

1. By administering neo-arsphenamin dissolved in sterile physiologic sodium chlorid solution instead of plain distilled water.

2. By preparing solutions of arspfenamin in a saline solution of sufficient strength to render the solution isotonic. The strength of the saline depends on the

concentration of the drug; for example, solutions of 0.6 gm. of arsphenamin in 120 c.c. or more, and of 0.4 gm. in 80 c.c. or more, may be made with physiologic sodium chlorid solution, whereas more concentrated solutions require from 0.3 to 0.7 per cent. saline as described above to secure isotonic solutions, according to the concentration of the solution of arsphenamin the physician is accustomed to prepare. The strength of the saline is the same for solutions of both the monosodium and disodium salts. Probably sterile physiologic sodium chlorid solution may be used for preparing the concentrated solutions of arsphenamin; but the resulting solutions would be hypertonic. These hypertonic solutions, however, are not likely to prove hemolytic, as experiments have shown that solutions of sodium chlorid in distilled water may be as high as 7 per cent. before producing hemolysis of fresh citrated human blood.

3. By avoiding the intravenous administration of concentrated solutions of arsphenamin for the reasons already given, concentrations of 0.6 gm. of arsphenamin in 60 c.c. or less of water or isotonic saline markedly increase hemolytic activity; more dilute solutions, as 0.6 gm. in from 120 to 180 c.c. of water or saline, are much less hemolytic.

4. By giving the injections slowly rather than rapidly, and particularly if concentrated solutions are being administered with a syringe; with slow injections there is more opportunity afforded for dilution of the hemolytic solution of arsphenamin with blood plasma and consequent reduction in hemolytic activity.

5. By avoiding the use of an excess of sodium hydroxid; whether solutions of the disodium salt are less toxic than solutions of the monosodium salt is yet to be determined in a conclusive manner. From the standpoint of hemolysis alone, the solution of monosodium salt (just enough alkali added to neutralize and "clear" the solution) is preferable to solutions to which one third excess of alkali has been added; probably the practice of adding enough alkali just to neutralize the solution plus one fifth more will prove the best practical procedure.

CONCLUSIONS

1. All solutions of arsphenamin are hemolytic, owing primarily to the direct hemolytic activity of arsphenamin itself.

2. Solutions of arsphenamin in isotonic saline solution are from three to ten times less hemolytic than solutions in water.

3. The hemolytic activity of solutions of arsphenamin in water and isotonic saline is unavoidably increased by the addition of sodium hydroxid for purposes of neutralization; the addition of an excess of alkali increases hemolytic activity.

4. Concentrated solutions of arsphenamin in water and isotonic saline are more hemolytic than dilute solutions.

5. Neo-arsphenamin is not hemolytic.

6. Dilute solutions of neo-arsphenamin in water, as 0.9 gm. in 90 c.c. or more of water, are hemolytic, owing to hypotonicity of the solution. Concentrated solutions, as 0.9 gm. in 30 c.c. or less of water, are not hemolytic, owing to the presence of sufficient inorganic salts from the drug to render the solution approximately isotonic.

7. To avoid hemolysis in the administration of dilute solutions of neo-arsphenamin, sterile physiologic

sodium chlorid solution prepared of freshly distilled water should be used; when the concentrated solutions are administered (each 0.1 gm. dissolved in 3 c.c. or less), sterile distilled water may be employed.

8. The degree of hemolysis produced by the administration of arsphenamin may be lessened (a) by using instead of water sterile saline solutions of such strength as to render the solutions isotonic; (b) by avoiding the administration of concentrated solutions; (c) by carefully neutralizing and "clearing" the solution with sodium hydroxid, counting the drops or otherwise measuring the amount necessary, and adding not more than a fifth of this amount in excess, and (d) by giving the injections slowly so as to permit gradual mixing and dilution of the solution with the blood.

DIFFERENCES IN PATHOLOGY OF PANDEMIC AND RECURRENT FORMS OF SO-CALLED INFLUENZA

DOUGLAS SYMMERS, M.D.

Director of Laboratories, Bellevue and Allied Hospitals

WITH THE COLLABORATION OF

MORRIS DINNERSTEIN, M.D., AND A. D. FROST, M.D.

Pathologist and Pathologic Intern, Respectively, Bellevue Hospital
NEW YORK

In New York City the first recurrent epidemic of so-called influenza, now fortunately at an end, presented certain noteworthy differences from the pandemic disease which prevailed in the latter part of 1918. The recurrent disease, while it incapacitated thousands, pursued a milder course, complicating pneumonias were relatively few, and the death rate, of course, did not approach the appalling figures of the previous eruption. On the other hand, the recurrent disease was characterized by a greater variety of pulmonary lesions—among other things, by concomitant semipurulent pleural exudates, by multiple pleural and subpleural abscesses, by frequent and extensive purulent invasion of the interlobar and interlobular septums of the lungs, by the formation of solitary, oftener multiple, discrete or confluent abscesses of the parenchyma, and by an extraordinary range of pneumonic lesions. The pathologic anatomy of the recurrent disease is important, not only from the standpoint of the diagnosis and treatment of the acute process, but also because the nature and distribution of the anatomic changes are such that we may expect both immediate and remote sequelae, some of which will probably demand operative interference.

The pandemic of 1918 is fresh in memory; but for purposes of comparison it may be recalled that the disease was strikingly abrupt in onset and that pneumonic complications were seldom absent, that they occurred early, progressed with amazing rapidity, and yielded a high mortality. At necropsy, the changes in the lungs were so constant that the anatomic diagnosis of so-called influenzal pneumonia could be postulated with almost absolute certainty, even in the absence of any knowledge of the clinical history. Variations occurred, of course, but were numerically inconsiderable. For example, in the first epidemic, the pleura was almost invariably free from signs of exudate. The inflammatory changes in the lungs, commencing in the deeper portions of both lower lobes apparently simultaneously, and progressing rapidly,

toward the periphery, often spared many intervening or surface lobules. The pleura almost always escaped literally, it would appear, because death took place before the pleura had time to react. In certain localities, empyema frequently occurred as a sequel to pneumonia; but the rapidly fatal pneumonias were seldom actually accompanied by inflammatory changes in the pleura. In the recurrent epidemic, on the contrary, many hundreds came down with a disease of comparatively trifling proportions; pneumonic complications, when present at all, were late and progressed without unusual rapidity. In the recurrent disease, the anatomic picture was extremely variable, so much so that, in order to classify the pleural and pulmonary changes, one must resort to the process of grouping; and between groups and the individual members of different groups there are numerous gradations.

DEATH FROM ASPHYXIA WITHOUT PNEUMONIA

Near the close of the epidemic of 1918, one of us¹ described a variety of so-called influenzal infection which was characterized anatomically by generalized intense congestion of the viscera, without evidences of pneumonic lesions, or attended by lesions of such small size as to be negligible. Death was accompanied by signs of asphyxia and, at necropsy, the right side of the heart was found to be immensely distended by deep bluish black fluid and clotted blood. The lungs were large, heavy and deep bluish, and the pleura was thin, smooth and glistening. On section, the cut surface was of the smoothness of velvet, and pressure yielded large amounts of dark fluid blood with or without an admixture of dirty, pinkish, edematous fluid. The mucosa of the larger bronchi was covered by a thin sheeting of whitish exudate, beneath which the membrane was swollen and intensely injected. Virtually every other organ in the body was injected to a corresponding extent. In the recurrent epidemic we have encountered five cases of identical nature. In all of them poisoning by wood alcohol was suspected because of the intense and widespread injection of the tissues, particularly the lungs and brain. Chemical investigation of the viscera in every case, however, was negative. Of the cases observed in 1918 and 1920—seven in all—the clinical histories were obtainable in six and showed that the patients had been ill for periods varying from a week to twenty-one days with cyanosis and generalized aches and pains, prostration, elevation of temperature, injection of the pharynx, and numerous moist and squeaky râles scattered over both sides of the chest. In two cases, signs of meningeal irritation were present in the form of muscular twitchings. In one case of the seven, death was sudden.

EMPYEMA AND PULMONARY ABSCESES

In the recurrent epidemic, forty-five cases were investigated by necropsy at Bellevue Hospital. Of this number, the pleura was involved in twenty-seven (60 per cent.). Of the twenty-seven cases, effusions occurred into the pleural cavity in eighteen, or forty per cent. of the total number of cases observed at necropsy; in twelve cases (26.6 per cent.), the effusions were semipurulent and unilateral in distribution, and in two cases bilateral; the remaining four were frankly purulent—two bilateral and two unilateral.

Of the twenty-seven cases of pleural involvement, multiple small subpleural abscesses occurred twelve times (44.4 per cent.) and of these, six were associated with semipurulent effusions and one with frank empyema. All of the seven cases of small subpleural abscesses associated with pleural effusions were found to be accompanied by abscesses in the parenchyma of the lung, the latter being relatively much larger in size. In the remaining five cases of subpleural abscesses, purulent foci in the parenchyma of the lung were absent, and there were no signs of pleural effusion, although the pleura was the seat of edematous fibrinous exudate in every instance. The association of multiple subpleural abscesses with pleural effusions and with abscesses in the parenchyma of the lung is of obvious surgical significance. On the other hand, it appears that multiple small subpleural abscesses may exist alone without giving rise to secondary effusions into the pleura. In the presence of such abscesses, however, it would be rather far fetched to assume that an accompanying effusion represents an independent infection of the pleura. While we have no anatomic evidence to offer that subpleural abscesses of the type described in this paper bear a direct causative relationship to empyema, it is quite probable that if an individual with small subpleural abscesses survives sufficiently long, rupture of or seepage through might readily infect the pleura with the secondary formation of seropurulent or purulent effusions. In short, in the recurrent disease there were cases of pleural effusion, purulent or semipurulent, which were associated with a combination of subpleural and parenchymal abscesses; there were other cases in which subpleural abscesses occurred alone and were not associated with effusions into the pleural cavity; in still other cases, pleural effusions occurred independently of abscess formation either in the pleura or in the lungs.

Of the forty-five cases, sixteen were associated with the presence of intrapulmonic abscesses (35.5 per cent.). In only one of these cases was the abscess solitary. The others were multiple, of irregular distribution, some bilateral, others unilateral, some in the lower lobes, others in the upper. The abscesses varied in size from minute affairs to purulent foci approximating 2 or 3 cm. in diameter. In one case, the upper lobe of the lung was almost completely replaced by multiple discrete or intercommunicating cavities.

THE PLEURAL CHANGES

The inflammatory changes in the pleura presented marked variations:

(a) In those cases of pneumonia in which the changes in the lung were obviously of the more acute variety, localized sheets of edematous fibrinous exudate were scattered over the surface of the consolidated lung, and when stripped away left an opaque, finely granular, deep bluish surface, scattered through which innumerable minute hemorrhagic specks were often discernible. In such cases, the exudate was practically never attended by the excessive accumulation of fluid in the corresponding pleural cavity.

(b) A second group of cases was characterized by the extensive deposit of fibrinous material over the surface of the lung, the membrane being thick, tough, opaque, dirty yellowish white, firmly attached, and often thrown into innumerable small corrugations. These membranous deposits were obviously in proc-

1. Symmers, Douglas: The Significance of the Vascular Changes in the So-Called Pandemic Influenza, *New York M. J.* 110:789 (Nov. 15) 1919.

ess of organization, and were invariably associated with excessive accumulation of semipurulent fluid exudate in the pleural cavity.

(c) In a third group of cases, the pleura was the seat of diffuse or patchlike collections of succulent, yellowish exudate which penetrated the lung substance at irregular intervals. Section of the consolidated lung in such cases showed thick, edematous prolongations extending from the pleura and surrounding individual lobules or small groups of lobules, not alone at the periphery of the lung, but deep in its substance. In many instances the interlobar septums were extensively invaded, the lobes were firmly glued together, and not infrequently collections of fluid exudate were included between them.

(d) In a fourth group of cases, the pleura presented solitary or multiple, pea-sized or slightly larger, rounded projections which were yellowish, soft in consistency, and, on section, released moderately thick, yellowish, cloudy fluid. These small abscesses lay in or immediately beneath the pleura and were often associated with quantities of seropurulent fluid in the dependent portions of the cavity. The intervening pleura was usually the seat of irregular or diffuse collections of edematous fibrinous exudate. The external covering of the abscesses was intact as far as the unaided eye could determine. Microscopic examination of the pleura in these cases showed the presence of rounded or elongated, circumscribed masses of polymorphonuclear leukocytes enclosed in a meshwork of finely fibrillated fibrin, the whole lying in or just beneath the pleura, sometimes surrounded by a thin but distinct layer of connective tissue representing, apparently, the result of proliferation of the walls of the lymph vessels. In certain of these minute abscesses the limiting connective tissue contained small, injected blood vessels.

It is obvious that the changes in the pleura are of extreme importance, not only from the standpoint of immediate effects, but because they are such that, if the patient survives, sequelae may be expected in a certain proportion of cases in the form of organization of the pleural membranes, with complete or partial obliteration of the cavity and interference with the movements of the corresponding lung, chronic diffuse or sacculated pleural or interlobar empyemas, and chronic interstitial interlobar pleuritis or interlobular pneumonia following organization of the exudate in the pleural extensions. In the same way, one seems justified in the prediction that residuums of pulmonary abscesses may occasion trouble in a certain number of cases in the form of gangrene of the lung following invasion by putrefactive bacteria, organization of the abscess walls with the overgrowth of connective tissue, and the formation of bronchiectases, expectoration of pus from bronchial fistulas, and the like.

PULMONARY LESIONS

In the pandemic of 1918, pneumonia was an almost constant occurrence. The prevailing type was a confluent lobular hemorrhagic and exudative lesion of bilateral distribution associated with areas of acute vesicular emphysema. In the recurrent disease, as we saw it at Bellevue Hospital, the attendant pneumonia conformed to no anatomic type. Of the pulmonary changes, the nearest approach to uniformity was found in the five cases marked by diffuse and intense congestion of the lungs and of virtually every other organ

in the body, with dilatation of the heart and death from asphyxia without signs of pneumonia, or with pneumonic foci which were numerically and geographically insignificant. Of the forty-five cases, only three were sufficiently characteristic to be classified with the variety of pneumonia that prevailed in the pandemic sweep. The remaining thirty-seven cases represented a conglomeration of pneumonic lesions, scarcely any two of which bore the same essential features. Among these, however, we were enabled to recognize a group, the members of which seemed to bear a certain general resemblance to the confluent lobular pneumonia of 1918. In these cases both lungs were involved, the lower lobes to a greater extent than the upper. The pleura covering the consolidated areas was irregularly strewn with fibrinous exudate and more or less richly sprinkled with hemorrhagic petechiae, and areas of acute vesicular emphysema were occasionally to be observed. The splotchlike hemorrhagic extravasations in the pleura, so frequently encountered a year ago, were seldom discernible. On the other hand, the consolidated portions not uncommonly showed large nodular or streaklike, firm, dark slate-blue elevations which, on section, revealed a smooth, velvety, bluish black surface, rich in blood—the so-called marantic infarctions or, better, massive hemorrhagic extravasations. The cut surface of the lungs as a whole presented extreme variations both in appearance and in consistency, owing to different combinations of dull reddish or deep bluish or grayish red lobular consolidations, confluent lobules of dull white appearance and semifluid consistency, inflammatory edema, abscess cavities varying in size from the head of a large pin to that of a crabapple, and filled with moderately thick whitish pus, the picture being still further complicated on occasions by the intersection of cream colored bands of infiltrated pleura that surrounded lobules or groups of lobules or that bound one lobe to another. In addition, the mucosa of the larger bronchi was swollen, deep bluish red, and of velvety smoothness. In three cases, large portions of a lobe were consolidated in such fashion as to resemble ordinary croupous pneumonia.

We do not mean to convey the impression that any single group of pneumonias in the recurrent epidemic presented the above described features with anything approaching regularity. On the contrary, as we have already stated, no two sets of pneumonic lungs presented the same essential features in the same essential combination as did the prevailing pneumonia of the pandemic year. Nevertheless, it is possible to select individual features from the array of pneumonias that accompanied the recurrent epidemic, and from them to reconstruct a composite picture of the pneumonia which characterized the pandemic.

Microscopically, the changes in the lung were correspondingly variable. The capillary vessels were universally engorged, intra-alveolar hemorrhages were frequent—sometimes discrete, at other times confluent. Certain vesicles were partially or completely filled by coagulated serous fluid, entangled in which were a few red cells or an occasional round cell. Other vesicles were filled by polymorphonuclear leukocytes and fibrin, and through necrosis and confluence of these, the majority of abscesses appeared to arise. The frequent and abundant appearance of fibrin was in contrast to the lungs of the pandemic disease, in which fibrin threads were rarely demonstrable and then in isolated

localities and small numbers. The interlobar pleural extensions were frequently enormously thickened through the infiltration of polymorphonuclear leukocytes and the deposition of variable quantities of fibrin. Most of these prolongations were ribbon-like in shape but not infrequently became oval or rounded and centrally necrotic; in this way, other abscesses were formed. In still other instances, the intervesicular venules and arterioles were thrombosed, and the exudate in the immediate vicinity showed large areas of necrosis. The smaller bronchi were distended by polymorphonuclear leukocytes, and their epithelial cells were desquamated.

HEART

In the pandemic of 1918, the heart muscle in the majority of cases was deeply congested but otherwise well preserved, both as far as the naked eye and microscopic changes were concerned. In the recurrent epidemic, acute parenchymatous degeneration occurred with great frequency, the heart muscle being flabby, opaque and friable. The immediate cause of death in both epidemics was to be found in immense dilatation of the heart, particularly the right side, the cavities of which were often filled to the point of distention by deep bluish red fluid and partially clotted blood. In one of the Bellevue Hospital cases during the recurrent epidemic, the pericardium was the seat of a semipurulent effusion out of which a pure growth of pneumococcus was secured. With this exception, the pericardium showed no changes worthy of record.

KIDNEYS

In the recurrent epidemic, acute parenchymatous degeneration of the kidneys occurred more frequently and in a more severe form than in the previous disease, the kidneys often being swollen, edematous and flabby, easily torn, and their markings obscured or irregular in distribution. Microscopic examination revealed, in addition to widespread congestion, granular changes in the epithelial cells of the convoluted tubules, occasionally in those of the glomerular tufts.

JAUNDICE

Of the forty-five cases investigated postmortem at Bellevue Hospital, jaundice occurred in only four, and was slight in extent, being limited to the face and upper portions of the chest. At necropsy, a number of factors appeared to participate in its production, namely, congestion and edema of the papilla of Vater and the surrounding mucous membrane of the duodenum, and the presence of mucoid secretions in the larger bile ducts, together with congestion and parenchymatous degeneration of the liver proper.

MISCELLANEOUS COMPLICATIONS

In the recurrent epidemic, degenerative changes in the rectus muscles were observed in Bellevue Hospital only once, and were of mild degree (Zenker's degeneration). In the previous epidemic, this variety of muscle change was encountered in a considerable proportion of cases, and not infrequently was attended by rupture and extravasation of large quantities of blood into the sheath of the muscle, occasionally followed by secondary infection and abscess formation. In another case in the recurrent epidemic, an abscess was found at the hilum of the right testicle associated with a solitary abscess of the upper lobe of the right lung occurring

in a hemorrhagic variety of lobular pneumonia. The same patient presented multiple effusions into the joints.

BACTERIOLOGY

Bacteriologic examination of the pleural fluid removed surgically and sent to the laboratory, together with that encountered at necropsy, revealed streptococci in most instances, occasionally *Staphylococcus aureus* and pneumococci. Bacteriologic examination of the pus in the intrapulmonary abscesses almost invariably yielded a pure growth of *Streptococcus hemolyticus*, but occasionally *Staphylococcus aureus*. In three cases, *Streptococcus hemolyticus* was isolated in pure culture from the blood. In the pneumonic exudates themselves, the prevailing micro-organism was a streptococcus. In occasional instances, influenza bacilli and pneumococci were isolated in combination with one another or with streptococci. There were three cases in which massive portions of a lobe were consolidated in such fashion as to resemble ordinary croupous pneumonia. In all of these the exudate was sticky. In two, *Bacillus mucosus-capsulatus* was isolated, in the other *Streptococcus mucosus*. In three other cases, streptococci were isolated from the blood during life; and all of them, at necropsy, presented abscesses of the lungs.

SUMMARY AND CONCLUSIONS

1. The first recurrent epidemic of so-called influenza in New York presented anatomic variations from the pandemic disease of a year before, (a) in the form of frequent and widespread inflammatory involvement of the pleura characterized by semipurulent and purulent exudates occurring in immediate association with pneumonic changes; (b) by multiple small pleural or subpleural abscesses; (c) by purulent infiltration of the interlobular and interlobar pleura, and (d) by solitary, oftener multiple, discrete or confluent intrapulmonary abscesses varying in size from a few millimeters to several centimeters.

2. In the pandemic disease of 1918, the participation of the pleura in the pneumonic process was conspicuous by its rarity. In the recurrent epidemic, pleural involvement occurred in 60 per cent. of all cases; and in 40 per cent., purulent or semipurulent effusions were present.

3. In the epidemic of 1918, intrapulmonary abscesses were virtually unknown accompaniments of the pneumonic process. In the recurrent epidemic, they were encountered in 35.5 per cent. of all cases. Of the total number of cases attended by pleural involvement (twenty-seven in all), multiple small pleural or subpleural abscesses occurred in twelve, or in 44.4 per cent.

4. As a result of the recurrent disease, sequelae may be expected in the form of (a) organization of the inflamed pleural membranes with partial or complete obliteration of the cavity and interference with the excursions of the corresponding lung; (b) delayed, diffuse or sacculated pleural or interlobar empyemas; (c) fibrosis of the lung following organization of exudate in the interlobar and interlobular septums of the pleura, and (d) gangrene of the lung and bronchiectatic cavities following secondary changes in intrapulmonary abscesses.

5. In the epidemic of 1918, pneumonia was virtually constant, both in point of incidence and in conformation to type. In the recurrent disease, pneumonia was a relatively infrequent event, and the anatomic vaga-

ries in the distribution and structure of the lesions were so numerous that no two sets of lungs were similar in appearance, and often one lung differed markedly from its fellow.

6. In the pandemic disease of 1918, acute degenerative changes in the heart muscle, liver and kidneys were neither frequent nor intense. In the recurrent disease, they were both common and severe. In the pandemic, the blood cultures were almost invariably sterile; in the epidemic, streptococcal septicemia occurred, we estimate, in about 10 per cent. of all pneumonias.

YELLOW FEVER CONTROL IN ECUADOR

PRELIMINARY REPORT

M. E. CONNOR, M.D.

Field Director, International Health Board

GUAYAQUIL, ECUADOR

The files of the National Board of Health of Ecuador show that the first recorded epidemic of yellow fever in the country occurred in the city of Guayaquil in the year 1842, and it was estimated at that time that one half of the population of the city died from this disease during the epidemic.

Yellow fever was probably introduced into Ecuador from Panama by the earlier settlers soon after the appearance of the disease at Panama, and has probably been present in Ecuador since that time, notwithstanding the fact that the records of the sanitary department report as many as three consecutive months in one year having passed without a single recognizable case of the disease. It undoubtedly was present, but in a type so benign as not to be easily diagnosed, especially in children.

The Gorgas commission of the International Health Board in a world survey for endemic yellow fever centers reported that this disease could be "eradicated from the west coast of South America by eradicating it at Guayaquil, Ecuador," and recommended that the attack be made by destroying the stegomyia breeding places in that city.

Arrangements were entered into with the Republic of Ecuador for a cooperative campaign with its national health agency on the following basis:

1. The National Board of Health of Ecuador would supervise the isolation of yellow fever patients and fumigation of houses as might be attempted.
2. The International Health Board would concentrate its efforts on mosquito-proofing the necessary water receptacles, that is to say, antilarvae measures.

The built-up area of Guayaquil occupies about 3 square miles, has a population of 90,000, and contains nearly 6,000 buildings. The average annual rainfall is 60 inches, and occurs principally during the months of January, February, March and April—a relatively short and light rainy season for a tropical city. The elevation of the city above mean tide is about 2 meters, and the topography is that of a plane.

The water supply is taken from a river about 90 kilometers northeast of the city. The present supply provides for 40 liters per capita each day and is delivered from storage tanks through a system of mains for about four fifths of the city area. The ration of water is available in the morning for one and one-half

hours only. That part of the city in which it is not possible to make house connections is served by water venders and from public taps or fountains.

The scarcity of water, therefore, makes it obligatory on the residents to store sufficient water for their needs in tanks, barrels and like receptacles.

ANTILARVAE MEASURES

That yellow fever is a place disease is a generally accepted fact. The spot map of yellow fever cases occurring in the city of Guayaquil during the year 1918 brings this out quite clearly, and shows that the vast majority of cases reported up to November of that year occurred in the most densely populated section of the city, or rather in that section in which houses had been erected without any intervening space. A survey of this district revealed the important fact that the vast majority of homes were supplied with from one to twelve water tanks each, in addition to the barrels and smaller receptacles, while the outlying districts depended almost entirely on smaller receptacles, very few tanks being used. Many of the tanks inspected were uncovered or so badly covered that the mosquito experienced no difficulty whatever in gaining access to the water within. The barrels and other receptacles were all uncovered. All tanks inspected on this survey were found to contain the stegomyia larvae; the smaller receptacles were also breeding places, more especially for the culex; and in two instances I noted stegomyia larvae in tanks, while in barrels in the same room only culex larvae could be found.

The stegomyia is essentially a house mosquito, that is to say, it breeds, lives and dies in the same house, it does not fly for any considerable distance, and it avoids bright sunlight; only under rare circumstances is it to be found breeding in streets, yards or fields, at least in Ecuador, and up to now we have not found this extraneous breeding of sufficient importance to be considered a factor in the present campaign.

The antilarvae measures were started Nov. 25, 1918, and were based on the findings of the early survey. The first step was to mosquito-proof all tanks as soon as possible, and the organization concentrated its efforts on this work during the earlier weeks of the campaign.

A graph to be published later will show that yellow fever cases decreased rapidly as the tanks were made mosquito-proof; and when the number of breeding places in tanks were reduced to 5 per cent. of the total number inspected, the disease had been controlled, but was not considered eradicated. This reduction was taking place during the height of the rainy season and while receptacles of water, other than tanks, still remained stegomyia breeding places.

Nearly all tanks used in the city for conserving water are made in the country, are rectangular, and have a capacity of from 10 to several hundred gallons. The water enters the tanks from above, the inlet pipe resting on the top of one side of the tank; the outlet pipe is usually from 1 to 2 inches above the level of the tank floor, and even when the tanks are empty, so far as getting any water from them by means of the faucet is concerned, there always remains enough water in the tank for an ideal breeding place for the mosquito. This fact explains in part why tanks are a more desirable breeding place for the mosquito: this class of water container is seldom without water, and the surface of the water is disturbed only during the morning for one hour or so.

In the barrels and the smaller containers, conditions are not so favorable for the mosquito, as the water is always taken from these containers by means of a pail or large cup and always from above; consequently, during daylight hours there is considerable movement of the water surface which is not conducive to the selection of this class of receptacle as a breeding place by a mosquito of the habits of the *stegomyia*; and further, there comes a time rather frequently in the dry season when the barrel and similar receptacles are empty by reason of the scarcity of water or for purposes of cleaning the container, a condition that does not obtain with tanks, at least with the same frequency. It is fair to assume that if the *stegomyia* mosquito can exercise the instinct for self preservation, it will select and even hunt for water in a tank in which to deposit her eggs as offering a more favorable opportunity for the development of same as contrasted with chances in a barrel or similar receptacle.

The present campaign has been based on the thought that with a reduction of *stegomyia* mosquito breeding in water tanks there should be a reduction in the number of cases of yellow fever, and that if the effort is continued the disease will be eradicated. All containers of fresh water in or near human habitation have been treated; but the thought to be conveyed is that the tanks as water containers have been given first consideration.

There are nearly 7,000 water tanks in use in the city, and nearly 30,000 other containers to be inspected. The tanks have been covered with either copper screen, galvanized iron, or wooden covers. Of the three classes of covers, the galvanized iron has proved the most satisfactory and the cheapest; they do not admit of contamination of the water by rats, which is possible with copper screening; nor can they be taken and used for fire wood, as sometimes happens with wooden covers.

Great care is taken that the tanks are so covered that the mosquitoes cannot gain entrance to the water within. We impress on the people that the mosquito is a small insect and naturally can penetrate a small opening. Tanks with perfectly fitting covers are sealed, bearing the stamp of the service, in a manner that the cover of the tank cannot be raised without breaking the seal, and a broken seal indicates to the inspector that a careful inspection of the tank must be made to determine whether the cover has been off long enough for the mosquito to deposit her eggs within.

Public opinion for the work was created through the press, public lectures, posters, handbooks, etc. Yellow fever had so long handicapped and actually retarded the progress of Guayaquil and Ecuador that the public was ready to cooperate in any measure that would aid in the control of this disease, and this effort has been most intelligent and constant. Owing to the scarcity of water, especially in the dry season, it was highly desirable that we should adopt some measure that would free the water containers of mosquito larvae and at the same time conserve the water to the people, and accomplish this result economically. We experimented with different species of fish to determine their usefulness as mosquito larvae consumers.

The first variety of fish used is known locally as the "huaijas," a member of the perch family. This fish readily eats mosquito larvae, but soon tires of its existence in a barrel or small receptacle, and will jump

3 and sometimes 4 feet to free itself from the container. The jumping properties are most often exhibited during the night. It will be readily seen that even when people are willing and anxious to conserve the fish in their water containers, they can hardly be expected to watch them during the night. To counteract this jumping, the service supplied covers for the barrels; but here again we encountered difficulty in keeping the covers on the barrels, and there are good local reasons why it was not desirable to insist that all barrels be equipped with covers and the water drawn off by faucet. We were forced to abandon the huaijas, on account of its jumping, for the chata, a small fish which proved to be a voracious eater of mosquito larvae. It has the additional property of spending the greater part of its time at the surface of the water; but when any one approached the container, the chata would immediately swim to the bottom, remaining there until the cause of its fright had been removed.

The chalaco also was tried out and has given very good results. Top minnows or "millions," were given a trial, and are quite satisfactory for certain class of containers. These fish are very delicate and do not survive long in the ordinary container unless some care is given to them. As long as fish are available, they will be used for all containers other than tanks.

The present campaign was actually started, Nov. 25, 1918, with twelve sanitary districts. The number of districts was gradually increased up to twenty-nine. This number was maintained for a few months, when reduction was permissible. Oct. 1, 1919, the city was redivided into ten sanitary districts. The inspection cycle was arranged so that every home in the city should be visited at least once every seven days, including Sundays. Sanitary inspectors started in their districts on Monday, and those not able to conclude on Saturday were aided by auxiliary squads.

On the farms outside the city of Guayaquil, all large containers were eliminated; and as these farms are usually located on the river and the homes of the laborers on the banks of the river, it was decided to recommend that receptacles holding not more than 5 gallons of water be used in place of barrels. It had previously been observed that the vast majority of the laborers do not use in their homes more than 5 gallons of water in twenty-four hours. Bathing, washing of clothes, etc., is usually done in the river, so that there is really no need for conserving water longer than twenty-four hours in the homes. By this method it is believed that the *stegomyia* mosquito can be eliminated in those areas where this measure can be put in force.

Death and Blindness Caused by Wood Alcohol.—Owing to the heavy increase recently noted in the number of deaths and cases of blindness resulting from the drinking of wood alcohol by those ignorant of its dangers, the National Committee for the Prevention of Blindness, 130 East Twenty-Second Street, New York, is sending broadcast special warnings of the tragic consequences which may follow the use of wood alcohol, denatured alcohol and medicated alcohol for beverage purposes. The harmful action of this poison comes not only from taking it internally, but may likewise be induced by breathing its fumes, and by absorption through the mucous membranes of the body. Its effect is usually noticeable very shortly after exposure. Within a few hours after drinking, acute headache is noted, usually accompanied by violent attacks of vomiting, body pains, extending over the region of the kidneys, and excessive dizziness. Vision may become impaired, total blindness occur, and death itself result.—*Illinois Health News*, October, 1919.

ARTERIAL HYPERTENSION*

FREDERICK M. ALLEN, M.D.

NEW YORK

The great importance of arterial hypertension or the conditions associated with it, as a widespread and apparently increasing cause of disability and death, is a self-evident incentive to investigation. At the same time it must be recognized that our knowledge of the subject is in a very confused state, as respects its phases of etiology, mechanism and treatment. Just as with diabetes, the literature contains almost every conceivable variety of opinions and suggestions. The first task of an investigator to choose is what seems significant and valuable among this mass of conflicting material, and the second is to build concrete facts with accurate methods in a clinical field which is still largely a morass of tradition and imagination.

THEORIES REGARDING THE CAUSES OF
HYPERTENSION

More or less restriction of salt has been employed for many years by some observant clinicians in the treatment of the various forms of nephritis. The first scientific foundation of both theoretical and practical importance is afforded by the work of the French school, beginning with Widál's demonstration of the rôle of the chlorids, particularly in the causation and treatment of edema, and with the application of this principle to hypertension by Ambard,¹ Combe,² Laufer³ and others. Similar results were obtained in arteriosclerosis by Bayer;⁴ but with only a few exceptions the tests with nephritis in Krehl's clinic were negative or doubtful, and the general German experience was opposed to a strict relationship between retention of chlorids and elevation of blood pressure.⁵

In American literature, salt and fluid restriction in hypertension is mentioned casually and incompletely if at all, and the protein intoxication theory is undoubtedly the dominant one. Treatment consists chiefly in low protein diets, the elimination of supposed toxins, or the artificial reduction of pressure by drugs, bleeding, electricity, and the like. Mental and bodily rest is advised to a degree which largely terminates usefulness in life, and many conservative practitioners refrain from any serious attempt to reduce the pressure, and devote themselves to keeping the patient as comfortable as possible, with resignation as to the results.

There are various reasons for this confusion and pessimism. In the German work the cases were not always well chosen and the restriction of salt was generally inadequate, though this work does furnish evidence against any invariable association of hypertension and gross chlorid retention. On the other hand, whether or not protein has any influence on blood pressure, it is impossible to accept Ambard's assertion that it is harmless in nephritis. Ambard considers fluid restriction unnecessary, and in adopting milk diet he comes back to the identical therapeutic program used

by the followers of the intoxication hypothesis. The fluid restriction of Laufer, who accepts von Noorden's limit of a liter daily without reckoning the important additional quantities contained in the food, is too lax for the worst cases. Likewise a much stricter exclusion of salt than represented by milk diet is essential for results in really severe cases. These inaccuracies are responsible for an unnecessarily high percentage of cases of absolutely or relatively irreducible hypertension in French, German, American and all other records, and also for the unnecessarily frequent and early deaths from apoplexy, cardiac failure, pulmonary edema and convulsions (misnamed uremic). For the same reason there have been no differences in therapeutic results sufficiently marked to establish any one theory to the satisfaction of all parties.

RESTRICTION OF WATER AND SALT

It would be wrong to ignore the unknown and uncontrollable factors in hypertension and the unsolved problems which they present. But any practitioner who will conform his treatment to one reasonable and definite condition, namely, the necessity of the organism to force a filtrate of water and dissolved substances through a damaged and partially blocked glomerular filter, can readily demonstrate for himself the compensatory element in the hypertension, by observing the fall in pressure and the relief of some attendant symptoms when proper diet reduces the quantity of this filtrate to a minimum. The opposite treatment under the intoxication hypothesis, through unsuitable diets and attempts at "flushing out," entails much harm. In some hypertension cases the mere reduction of the overload of salt and water brings relief which is comparable to the benefits of diet in diabetes.

Fuller laboratory study, particularly by blood analyses, contributes new information of theoretical, prognostic and therapeutic importance. Among the nephritic cases treated in our clinic to date, there have been twenty examples of marked hypertension. Most of these were treated in private hospital status, but four were outpatients. The observations are necessarily empiric, and are subject to modification from wider clinical experience, and particularly to more fundamental and decisive interpretations when animal experiments become available. Numerous data of these cases, function tests according to Ambard's principles, and details of individual histories and results, must be reserved for a more complete publication at a later date.

It may suffice here to state that the patients' ages ranged from 25 to 69 years, with the usual predominance of those past 40. All the cases were of chronic type. Their severity was mostly too great to yield to mere rest and hospital care, and some were known as highly severe cases which had proved intractable to a variety of customary treatments for several years. Bleeding was used temporarily in three critical cases, and brief experiments have been tried with some other measures; but in general the patients were not kept in bed or confined to the house but were treated entirely by diet.

To establish the general principle, the effects of sudden dosage with salt or water in suitable cases are illustrated by two experiments.

In the first experiment (Table 1), attention may be called to the absence of real retention of either salt or water (contrary to the French reports), and to the

remarkably high plasma chlorid figures⁶ and the elevation of blood pressure accompanying these.

The second experiment (Table 2) was performed on a different patient. The plasma chlorid percentage was not high, and fell lower with the water drinking, while the blood pressure rose markedly.

The first patient received salt, but showed no effect from a corresponding test with water alone. Because of the close relations between salt and water, it is

difficult to distinguish accurately between their effects, and space requirements necessitate leaving other tests to a later publication. The rise in pressure in both cases was accompanied as usual by the subjective symptoms of headache, dizziness, weakness and general malaise. Precautions were taken so that no patients suffered harm from such tests, but in severe cases there is danger that the reckless administration of either salt or water may cause alarming symptoms and even death. The accuracy of the tests is often interfered with by a protective diarrhea which also prevents dangerous disturbances.

The results of a short test may be negative in some patients or at some stages, and bad effects may become

evident only after some days. The effects of salt are in general more powerful and obvious, as demonstrated by the success of Ambard and others in numerous cases. A very close restriction of water may be impracticable at the beginning of treatment, because of the salt stored in the patient's body and the inadvisability of imposing any real suffering from thirst. Also in many cases no rigid fluid restriction is necessary, and moderate quantities (from 1 to 3 liters daily) may be actually beneficial for flushing out salt or nitrogen. But the prolonged combination of excessive fluid and

little salt possibly involves osmotic and eliminative difficulties which are responsible for the anasarca, pulmonary edema and cardiac failure sometimes described in connection with long continued salt-poor diet.

No rigid classification, either anatomic or functional, of the cases listed in Table 3 was attempted, partly because the experience is insufficient, and partly because every case of nephritis is in some respects an individual problem, in which tests of the efficiency of different functions should be made and individual treatment prescribed accordingly. Different tests will give different classifications, and there are presumably types of cases not shown in this series. The phenol-sulphonphthalein excretion is given here as one indication of renal action, but the complete publication will include other function tests. The data shown are otherwise limited to those which seemed most essential for treatment and prognosis. The order of cases is not merely consecutive or accidental, but forms a series based on these data.

* Parentheses in the systolic pressure column indicate that the pressure in these cases was repeatedly near 300 m.m., but the actual pressure on beginning dietetic treatment was 215. In Case 19 this reduction had been accomplished only by heavy bleeding in another hospital.

CASES OF PURE HYPERTENSION

The first cases are more or less typical examples of so-called pure hypertension. One of them (Case 2) had been observed for over a year, and occasional urinalyses, even when the blood pressure was as high as 300 m.m., never showed albumin. In recent months, with more frequent urinalyses, traces of albumin have sometimes been found. The others of this group have traces of albuminuria. Omitting individual peculiarities, it may be said that this group is characterized by activity of excretion and apparent absence of retention in tests with nitrogen, water and even salt. The kidney retains power to concentrate, and both the blood urea and the urea function according to the Ambard principle may be fully normal. But the chlorid threshold, whether determined mathematically or by salt privation, is high, and these patients purchase their apparent efficiency of salt excretion at the price of abnormally high blood salt and blood pressure. Extraordinary strictness of salt-free diet may be necessary to control these, and the therapeutic success corresponds to the restriction in salt intake. This single feature some-

6. For chlorid method, see Donleavy, J. J.: *J. Biol. Chem.* 37: 551 (April) 1919.

times makes the difference between health and invalidism. While protein and water create no symptoms, on general principles they should be limited to some extent. Without assuming that all possible kinds of cases are represented in this list, and without overlooking other abnormalities revealed by sufficiently thorough study, it can be stated that pure hypertension, so far as it has occurred in this series, has been essentially a salt nephritis.

HYPERTENSION WITH KIDNEY IMPAIRMENT

As all standards of kidney function are to some extent arbitrary, this group passes by gradual transition into the second and larger group, in which there is obvious impairment of several kidney functions, as indicated by retention of urea and other products, impaired excretion of urea and chlorids by Ambard's laws, more or less fixation in the chlorids and specific gravity of the urine, and especially chlorid retention with or without evident edema.

The degree of impairment in the nitrogen economy calls for corresponding restriction of protein, and influences the prognosis. But the hypertension is affected only through the salt and water functions. Careful fluid restriction is necessary as a rule, but attention should be given to the nitrogen retention thus entailed in certain toxic cases. This is an additional reason for limiting the protein intake, though it is well known that the percentage of blood urea is not an infallible index of danger. Even though chlorid retention be far greater than in the first group and the other signs more evident as stated, the actual chlorid threshold may be lower and the actual salt restriction required to control the pressure may be less stringent in the second group.

It is well known that retained salt may be diffused through edema fluid without raising the percentage in the blood. Patient 11 thus had much edema, and as this diminished, the chlorid percentage in the blood rose as shown in parentheses. With this proviso, the great majority of these cases had high chlorids in the blood plasma, and it is probable that the same will hold for the majority of all hypertension cases. But in approaching Group 3, we find a small group of hypertension patients with continuously low blood chlorids and low chlorid threshold, and often with normal or actually low blood urea.

HYPERTENSION WITH DIABETES OR SEVERE NEPHRITIS

The six closing cases of this table may be divided into two groups of three each. The first group includes three cases (15, 16 and 17) of diabetes. In them the prognosis is good with thorough treatment of the diabetes, sometimes with the aid of salt and water restriction and sometimes without it. Though there are presumably rare cases of intractable hypertensive nephritis associated with diabetes, there is generally the strong probability that proper treatment, associated with reduction of the blood sugar, will reduce the hypertension.

The last three cases of the table are nondiabetic, and have proved the most difficult and intractable of the entire series. Limitation of salt, protein and fluid, reducing the twenty-four hour urine volume below 300 c.c., has given symptomatic relief and more or less complete checking of retinitis, but the influence on the pressure has on the whole been slight and the reduction shown in the table has not been permanent. Notwith-

standing the innocent looking blood analyses, according to function tests these are cases of severe nephritis, and the worst element in their prognosis from the standpoint of hypertension seems to be the absence of a high blood chlorid before treatment.

LIMITATIONS IN TREATMENT

Certain precautions or limitations should be mentioned with regard to the practical application of these principles in treatment.

First, a diet which is reasonably satisfying and at the same time sufficiently poor in salt is not so easy to arrange as it may appear. Both physician and patient may sometimes believe conscientiously that strict abstinence from salt has been maintained, when analyses will show the blood chlorids undiminished and an output of from 5 to 10 gm. in the twenty-four hour urine. Such analyses are important for controlling the treatment, and no pressure is rightly called irreducible unless the daily chlorid excretion has been reduced to practically zero.

Second, some quantity of salt is considered indispensable in the permanent ration. This is stated as about 2 gm. for normal persons, but the limits for nephritics have never been determined. On the one hand, it is not certain that the intake need be as great when the output is obstructed. On the other hand, there may be danger in withdrawing salt from certain nephritics, especially with nitrogen retention, who seem to need much more than 2 gm. of salt for its diuretic action to ward off uremia. As a rule, the outstanding effect of undue salt privation has been weakness. It is necessary, therefore, to work out salt rations for individual nephritics which may range from almost zero to a considerable quantity.

Third, restriction of salt or fluid, like every dietetic treatment of organic disease, is only palliative. Success is not as uniform as in the treatment of diabetes, and complete or partial failures are more numerous. When the first results are more or less satisfactory, there is still reason to fear that the same patients may pass into a hopeless condition in the course of months or years. Furthermore, the most effectual relief of the hypertension demonstrates strongly that the essential trouble is more than mechanical. Reduction of the blood pressure nearly or completely to normal may still leave the patient an invalid, either from weakness due to the strict salt privation which is necessary to hold down the pressure, or still worse, if salt is given so as to allow the pressure to go up. They may also be subject to attacks of hypertension and accompanying symptoms from little or no evident cause. The greatest defect of the French work is the disposition of those authors to treat the entire question as a mere mechanical matter of salt retention. Obviously, even the mechanics of hypertension remains largely unsolved, and the fundamental condition thus far baffles both research and treatment.

Notwithstanding these limitations, the benefit of suitable chlorid restriction for hypertension is still great, in making the patients more comfortable, diminishing the danger of apoplexy, and possibly checking the progressiveness of the disorder. So many of these patients give a history of copious use of salt that this may be a possible contributory factor. Granting a primary infectious or toxic etiology of the renal or vascular damage, the prolonged irritation by the excess of salt and the wear and tear of the hypertension itself,

may well be regarded as a cause of progressive aggravation. By far the best and easiest results are obtainable in the earliest cases, when the hypertension is intermittent rather than continuous. Early diagnosis is therefore important, and in advance of the sphygmomanometer it may be hoped that chemical tests, such as for the blood chlorids and chlorid threshold (the normal values for which are still undecided), may give advance warnings to guide prophylaxis.

Such studies may also throw some light on the origin and the control of arteriosclerosis and some other disorders. One of the most interesting branches of the investigation has concerned ophthalmic disorders, and with the cooperation of several oculists, evidence has been gathered indicating that many cases of retinitis are due chiefly or solely to chlorids and are benefited by chlorid restriction. More cases of retinitis and of glaucoma are needed for this study. The promising study of salt metabolism will probably soon be extended more widely by those who are in position to undertake parallel determinations of various salts and to develop the more fundamental problems through animal experiments. The present investigation, which has had to be self-supporting to date, has been limited and superficial for lack of these things. The clinical facts collected, however, warrant urging that unfounded theories be discarded, the widespread abuse of drugs, particularly nitrites and iodids, stopped, and the possibilities of modern laboratory methods utilized for the guidance of treatment.

5 East Fifty-First Street.

INFECTION BY THE BROAD TAPEWORM, *DIPHYLLOBOTHRIUM LATUM**

M. W. LYON, JR., PH.D., M.D.
SOUTH BEND, IND.

While cases of infection by the broad tapeworm have been rather frequently reported in the United States in recent years, and most of them, like the present one, have occurred in immigrants who have acquired the infection abroad, yet because of the probability of the permanent establishment of this parasite in this country, it is desirable to record each case with as many details as possible.

The worm here recorded was casually handed to me in the early part of January of this year. The dark spots in each mature segment had been noticed, but the true nature of the parasite had not been fully appreciated. The specimen had been washed from the feces with which it was expelled by the patient. The head is lacking, although many of the immature segments immediately following the head are present. The specimen is in several pieces, and the combined length of them laid out without traction on a table is 6,230 mm. All the segments appear in excellent condition, and none appear atrophic or degenerated.

The patient presented almost no symptoms.

REPORT OF CASE

B. N., man, aged 39, Russian Jew, machinist, born at Bielostok, Poland, where he resided until he was about 19 years of age, spent the next six years, including the time of the war between Russia and Japan, and while with the Russian army, at various places in Siberia, such as Omsk, Tomsk, Irkutsk and Yakutsk. During these six years he ate much

uncooked fish. Although much fish had been eaten during his youth at Bielostok, he thinks it was well cooked by his mother. After the six years spent in Siberia he returned to Bielostok, and soon after came to the United States. In this country he spent one year in New York, six years in Chicago, and six in South Bend, Ind. He first knew he had a tapeworm eight years before, while he was living in Chicago, his knowledge being based on the fact that he passed fragments from 12 to 18 inches in length. These fragments appeared to him well preserved, and he says that they showed motility. He found segments only at the time of defecation. He never noticed any segments passed while he was in the Old World, but he suggested that, being younger, perhaps he was a careless observer and did not pay so much attention to himself. The patient said that he had always been well and had never consulted a physician until he wished the worm expelled in the latter part of December, 1919, and except when being examined for life insurance. He passed the insurance examination successfully. About three months before seeking treatment for tapeworm he had obscure abdominal distress; and he had another attack at the time he sought treatment. He consulted Dr. C. C. Terry of this city, by whom he was given aspidium. A few days later, when he had recovered from the effects of medication, the worm was submitted to me for identification. I was unable to get the patient for a blood examination until nearly two weeks after the worm had been expelled. Blood examination then revealed: erythrocytes, 5,148,000; leukocytes, 6,400; hemoglobin, 85 per cent., Sahli; polymorphonuclears, 56 per cent.; small lymphocytes, 28 per cent.; large lymphocytes, 7 per cent.; large mononuclears, 2 per cent.; transitionals, 3 per cent.; eosinophils, 3 per cent.; basophils, 1 per cent. The patient has the appearance of being in perfect health, and looks strong and robust.

COMMENT

There can be little doubt that this patient became infected with a broad tapeworm while living at Bielostok, which is one of the general regions where such worms are common, or in Siberia, where he knows he ate uncooked fish. He may have acquired it in this country, but that is very doubtful.

That the patient is and has always been robust shows that an anemia is not necessarily caused by the presence of this parasite. The fact that he passed well preserved and easily recognized segments is rather unusual¹. The absence of anemia, and the good condition of the segments passed as well as of the entire worm as subsequently passed, are in accord with the views that diseased or disintegrating worms are the chief cause of the anemia due to the absorption of products from disintegrating segments.²

This case has afforded an excellent opportunity for the parasite to become permanently established in this region of the United States. For the past six years many thousands of eggs must have entered the sewerage system of South Bend, very soon to reach the St. Joseph River and a short time later Lake Michigan. In both river and lake, hatching larvae must have been able to parasitize various fishes.

Probabilities as to When the First Birth Will Occur.—According to Knibbs, statistician for Australia, the probability of a nuptial first birth occurring in less than one year after marriage is 0.4946 for age 15 of the wife; 0.7770 for age 18; 0.9176 for age 21; the maximum, or 0.9771, for age 25; 0.9075 for age 30; 0.6748 for age 35; 0.3245 for age 40, and 0.0622 for age 45. The foregoing statistics are based on the supposition that the husband is approximately the same age as the wife. If he is younger or older than the wife, the probability will be affected accordingly.

SQUAMOUS-CELL EPITHELIOMA OF THE LIP

A STUDY OF FIVE HUNDRED AND
THIRTY-SEVEN CASES *

A. C. BRODERS, M.D.

ROCHESTER, MINN.

Of all the malignant neoplasms with which man is afflicted, few cause more concern and inconvenience than that of epithelioma of the lip. In the past, pathologists have been content to classify cancer of the lip as cancer, without any distinction as to the degree of malignancy. It is a well established fact that some cancers of the lip are fatal to patients and others are not. There must be a reason for this. One theory is that some persons are resistant to cancer, and this seems to be borne out in a certain percentage of cases.

Undoubtedly, a large proportion of cancer cells are destroyed by the defense cells of the body; of these, the fibrous connective tissue cell is the most important, since it cuts off nourishment from the cancer cells.

The endothelial leukocyte and lymphocyte evidently also play an important rôle in the destruction of cancer cells, for practically always they may be seen in the neighborhood of a cancerous growth. Foreign body giant cells that are most probably formed from the endothelial leukocytes are not infrequently found lying adjacent to cancer cells.

The most important factor in squamous-cell epithelioma of the lip seems to be the degree of cellular activity. The cells of some epitheliomas of the lip show a marked tendency to differentiate, that is, to produce a growth similar to the normal; the pearly body is an example. The pearly body corresponds to the horny layer of the epidermis. In other squamous-cell epitheliomas there is no differentiation whatever. In the large majority of growths whose cells show no

tendency to differentiate, or at least very little, there are many mitotic figures.

In studying these epitheliomas, therefore, it occurred to me that they should be graded according to differentiation and mitosis, special stress being laid on the former. The grading was made on a basis of 1 to 4, and absolutely independent of the clinical history. If an epithelioma shows a marked tendency to differentiate, that is, if about three fourths of its structure is differentiated epithelium and one fourth undifferentiated, it is graded 1; if the differentiated and undifferentiated epithelium are about equal, it is graded 2; if the undifferentiated epithelium forms about three

fourths and the differentiated about one fourth of the growth, it is graded 3; if there is no tendency of the cells to differentiate, it is graded 4. Of course the number of mitotic figures and the number of cells with single large deeply staining nucleoli (one-eyed cells) play an important part in the grading.

Some epitheliomas of the lip are very active and from the start show little or no tendency to differentiate; some grow more malignant with time, and others increase in malignancy and then retrogress. Unquestionably an epithelioma of a low grade of malignancy is made more malignant by irritation with chemicals such as hydrochloric or nitric acid, silver nitrate or arsenic paste.

Chronic ulcers of the lip, like chronic ulcers of the stomach, should be examined very closely

for cancer, provided syphilis has been eliminated. MacCarty¹ has demonstrated early cancer in the epithelium at or near the edge of gastric ulcers; practically the same process is found in early cancer or ulcer of the lip. In the lip the cancer starts in the stratum germinativum of the epithelium at or near the border of the ulcer. Not all cancers of the lip are preceded by ulcers, but the majority are.

I shall present the facts in statistical form and make the deductions, not from one, but from various standpoints: (1) the duration and size of the lesion; (2) the

CONCLUSIONS

1. The 537 cases of squamous-cell epithelioma of the lip in this series represent 26.85 per cent. of 2,000 cases of general epithelioma.
2. Squamous-cell epithelioma of the lip occurs more often in males than in females; the proportion is 49:1.

It occurs in patients past middle life; their average age is 57.3 years.

3. The disease occurs most often in farmers; they represent 56.7 per cent. of the cases.

4. A family history of malignancy plays a negligible part.

5. The site of the cancer was preceded by a sore or an ulcer in 63.3 per cent. of the cases.

6. About one fifth of all the patients do not use tobacco, while one half of the female patients do not use it.

7. Of the patients using tobacco, 93.33 per cent. smoke; 78.48 per cent. of these use a pipe.

8. A comparison of 500 men without epithelioma of the lip with the 537 patients with epithelioma of the lip shows that the percentage of tobacco users and non-tobacco users is practically the same; 78.6 per cent.

Fig. 3 (a 265421).—Typical depressed or ulcer-like epithelioma of the lip.

users and 21.4 per cent. nonusers in the former group, and 80.49 per cent. users and 19.51 per cent. nonusers in the latter group, but that the average age of the men

Fig. 4 (a 21283).—Marked leukoplakia of the lip, characterized by increase of (a) horny layer of epidermis, and (b) basal layer.

without epithelioma of the lip is about nineteen years less than the average age of the patients with epithelioma of the lip at the time of onset.

9. The most remarkable difference in a comparison of the patients with epithelioma of the lip and the men without epithelioma of the lip is in the method of smoking. The total number of pipe smokers in the former

cent., and the total number of cigaret smokers has risen to 59.04 per cent.

10. A history of injury plays a negligible part.

11. The duration of the lesion shows a marked variation, from 0.08 years to 28 years, with an average of 2.58 years.

Fig. 6 (a 98158).—Grade 1 epithelioma of the lip with marked differentiation; low degree of malignancy; patient well five years after operation; a, epithelioma; b, normal epithelium.

12. The greatest diameter of any lesion is 12.5 cm.; the average, 2.4 cm.

13. The lesion originated on the lower lip in 95.69 per cent. of the cases, on the upper lip in 3.55 per cent., at the left angle of the mouth in 0.56 per cent., and at the right angle of the mouth in 0.18 per cent.

TABLE 5.—PATHOLOGIC FINDINGS IN CASES IN WHICH LYMPH NODES AND SUBMAXILLARY SALIVARY GLANDS WERE REMOVED

Cases	No.	Per Cent.
No metastasis found	449	
Metastasis found	344	76.62
Submaxillary lymph nodes alone (one side)	105	23.38
Submaxillary lymph nodes and salivary glands (one side)	44	41.90
Submaxillary lymph nodes (one side) and submental lymph nodes	13	12.38
Submaxillary lymph nodes, salivary glands, and superior superficial cervical lymph nodes (one side)	7	6.66
Submental lymph nodes alone	6	5.71
Submaxillary lymph and superficial cervical lymph nodes (one side)	5	4.76
Submaxillary lymph nodes (both sides) and submental lymph nodes	6	5.71
Submaxillary lymph nodes (both sides), submental and anterior jugular lymph nodes (one side)	5	4.76
Miscellaneous (submaxillary lymph nodes and salivary glands, submental, cervical, parotid, supraclavicular and peribronchial lymph nodes; lung and liver, alone or in various combinations)	3	2.85
Submaxillary lymph nodes, total involvement	16	15.23
Submaxillary salivary glands, total involvement	92	87.61
Submental lymph nodes, total involvement	23	21.90
Cervical lymph nodes (one or more groups)	26	24.76
Superior deep cervical nodes	26	24.76
Inferior deep cervical nodes	3	7.89
Exterior jugular nodes	3	7.89
Anterior cervical nodes	24	63.15
Supraclavicular nodes, total involvement	8	21.05
Parotid lymph nodes, total involvement	1	0.95
Peribronchial nodes, total involvement	1	0.95
Lung, total involvement	2	1.90
Liver, total involvement	1	0.95
Submaxillary lymph nodes, total involvement on both sides	1	0.95
Cervical nodes, total involvement on both sides	13	12.38
	2	1.90

TABLE 6.—GRADE OF FIVE HUNDRED AND THIRTY-SEVEN CASES ON A BASIS OF 1 TO 4, ACCORDING TO CELLULAR ACTIVITY

Grade	No.	Per Cent.
Grade 1	85	15.82
Grade 2	333	62.01
Grade 3	113	21.04
Grade 4	6	1.11

DURATION AND SIZE OF EPITHELIOMA ACCORDING TO GRADE				
	Grade 1 Years	Grade 2 Years	Grade 3 Years	Grade 4 Years
Longest duration	10.00	25.00	28.00	2.00
Shortest duration	0.10	0.08	0.08	0.91
Average duration	1.43	2.77	3.33	1.29
	Cm.	Cm.	Cm.	Cm.
Largest size	5.00	10.00	7.50	2.00
Smallest size	0.20	0.30	0.20	1.80
Average size	1.23	2.28	3.25	1.9

EPITHELIOMA PRECEDED BY ULCER		
Grade	No.	Per Cent.
Grade 1	52	15.29
Grade 2	225	66.17
Grade 3	60	17.64
Grade 4	3	0.88

PROPORTION OF EACH GRADE PRECEDED BY ULCER		
Grade 1	61.17	per cent. of 85
Grade 2	67.56	per cent. of 333
Grade 3	53.09	per cent. of 113
Grade 4	50.00	per cent. of 6

INOPERABLE EPITHELIOMA ACCORDING TO GRADE			
Grade 1	Grade 2	Grade 3	Grade 4
0	12	7	2

14. Twenty-nine and five hundredths per cent. of the patients were treated with acid, paste or plaster, etc., before they entered the clinic.

15. Seventeen and eighty-seven hundredths per cent. of the patients were operated on before they entered the clinic.

16. Ninety-six and eight hundredths per cent. of the patients were operated on at the clinic.

Fig. 7 (a 64692).—Grade 1 epithelioma of the lip showing marked differentiation, although it is of a slightly higher degree of malignancy than the epithelioma shown in Figure 5; patient well seven years after operation; a, completely differentiated area; b, partially differentiated cells; c, normal epithelium.

17. In 87.01 per cent., the regional lymph nodes were removed.

18. Of the 449 cases in which the lymph nodes or salivary glands were removed, metastasis was demonstrated in 23.38 per cent.; the submaxillary lymph nodes were involved in 87.61 per cent.; the submaxillary salivary glands in 21.90 per cent.; the submental lymph

TABLE 7.—Continued

CAUSE OF DEATH OF PATIENTS OPERATED ON: DATA FROM HOME PHYSICIAN, OR PATHOLOGIC RECORDS OF THE CLINIC		No.	Relative, Per Cent.
Known cause	99		
Cancer of the lip	63	63.63	
Heart disease	5	5.05	
Nephritis	5	5.05	
Pneumonia	4	4.04	
Stomach trouble	3	3.03	
Paralysis	3	3.03	
"Following operation elsewhere"	3	3.03	
Fall	2	2.02	
Carcinoma of the stomach	1	1.01	
Tumor of the stomach	1	1.01	
Abdominal tumor	1	1.01	
Diabetes	1	1.01	
Carcinoma of the sigmoid	1	1.01	
Sepsis	1	1.01	
Tuberculosis	1	1.01	
Hepatic disease	1	1.01	
Cardiac and hepatic disease	1	1.01	
Sarcoma of the liver	1	1.01	
Lung trouble	1	1.01	
Unknown	25		
CAUSE OF DEATH OF PATIENTS WHO DIED IN THE MAYO CLINIC (ALL OPERABLE)			
Chronic nephritis and arteriosclerosis (more than 2 years after operation)			1
Epithelioma and abscess of the neck (52 days after operation)			1
Epithelioma (25 days and 4 months, respectively, after operation)			2
Pneumonia (few days after operation)			3
Sepsis (12 days after operation)			1
Total (1.55 per cent. of 516)			8
Actual operative mortality (0.77 per cent. of 516)			4

Fig. 8 (a 99884).—Grade 2 epithelioma of the lip; not so much differentiation as in epithelioma shown in Figure 6; patient died from epithelioma of the lip four and one-half years after operation: a, completely differentiated area or pearly body; b, undifferentiated cells.

TABLE 7.—RESULTS

GENERAL ULTIMATE RESULTS			
Patients traced (operable, 306; inoperable, 8) (58.47 per cent. of total)			314
Patients operated on			306
Patients dead (40.52 per cent.)			124
Patients alive (59.47 per cent.)			182
Good result (no recurrence (92.85 per cent. of 182))			169
Fair result (slight recurrence) (6.04 per cent. of 182)			11
Bad result (no improvement) (1.09 per cent. of 182)			2
DURATION OF LIFE SINCE LAST OR ONLY OPERATION, ACCORDING TO RESULT			
	Good Result Years	Fair Result Years	Bad Result Years
Longest	14.39	13.68	2.80
Shortest	1.25	0.96	0.49
Average	7.76	6.8	1.65
MORTALITY			
Deaths (42.05 per cent. of 314)			132
Deaths of patients with operable epithelioma (93.93 per cent. of 132)			124
Deaths of patients with inoperable epithelioma (6.06 per cent. of 132)			8

Fig. 9 (a 59017).—Grade 2 epithelioma of the lip; about the same degree of malignancy as in epithelioma shown in Figure 7; patient well more than seven years after operation: a, partially differentiated cells; b, undifferentiated cells.

TABLE 8.—TOBACCO USERS OPERATED ON

	Grade 1	Grade 2	Grade 3	Grade 4
Number of patients	37	118	37	3
Patients living	34 (91.81% of 37)	92 (77.96% of 118)	10 (27.02% of 37)	
Patients living, good result	33 (97.05% of 34)	85 (92.39% of 92)	10 (100% of 10)	
Patients living, fair result	1 (2.94% of 34)	6 (6.52% of 92)		
Patients living, poor result		1 (1.08% of 92)		
Patients dead	3 (8.10% of 37)	26 (22.63% of 118)	27 (72.97% of 37)	3 (100% of 3)
Cause unknown		6	5	1
Good result	2 (66.66% of 3)	6 (30.00% of 20)	7 (31.81% of 22)	
Fair result	1 (33.33% of 3)			
Poor result		14 (80.00% of 20)	15 (68.18% of 22)	2 (100% of 2)
Total good result (patient recovered from epithelioma and is living, or recovered from epithelioma and died from other cause)				Per Cent.
Total fair result (patient living with slight recurrence or died from other cause)				78.14
Total poor result (patient lived with no improvement or died from epithelioma)				4.37
				17.48

TABLE 9.—NONUSERS OF TOBACCO OPERATED ON

	Group 2	Group 3	Group 4
Number of patients	7	37	7
Patients living	6 (85.71% of 7)	29 (78.37% of 37)	4 (57.14% of 7)

DURATION OF LIFE AFTER OPERATION OF ALL PATIENTS WITHOUT METASTASIS		Years
Longest duration		10.19
Shortest duration		0.36
Average duration		3.68

DURATION OF LIFE AFTER OPERATION OF PATIENTS WITHOUT METASTASIS WHO ARE DEAD			
Good result—Patients did not die from epithelioma:			
	Grade 1	Grade 2	Grade 3
Number of patients	3	18	3
	Years	Years	Years
Longest duration	5.8	10.19	9.3
Shortest duration	3.5	0.36	2.02
Average duration	4.28	4.24	6.07
Fair result—Patients did not die from epithelioma but had slight recurrence:			
Number of patients			1
			Years
Longest duration			6.93
Poor result—Patient died from epithelioma:			
	Grade 2	Grade 3	
Number of patients.....	9	3	
	Years	Years	
Longest duration	4.51	1.52	
Shortest duration	1.00	0.51	
Average duration	2.15	0.95	

nodes in 24.76 per cent., and the cervical lymph nodes in 24.76 per cent.

19. In a division of the epitheliomas according to cellular activity, on a basis of 1 to 4, Grade 1 represents

Fig. 10 (a 72479).—Grade 2 epithelioma of the lip: *a*, epithelioma; *b*, normal epithelium; *c*, lymphocytes

15.82 per cent.; Grade 2, 62.01 per cent.; Grade 3, 21.04 per cent., and Grade 4, 1.11 per cent.

20. The average duration of the lesion according to grade is longest in Grade 3, 3.33 years, and shortest in Grade 4, 1.29 years.

21. The average size of the lesion according to grade is largest in Grade 3, and smallest in Grade 1.

22. Of the patients operated on and traced, 40.52 per cent. are dead and 59.47 per cent. are alive.

23. Of the living patients, 92.85 per cent. report a good result, having been free from the disease on an average of 7.76 years.

24. Of the patients operated on who have died, concerning whom information has been received, 63.63 per cent. died from epithelioma.

25. Eight, or 1.55 per cent., of the patients who were operated on died in the clinic, while the actual operative mortality was only 0.77 per cent.

26. The users of tobacco who were operated on did not obtain quite so good total good results as the non-tobacco users; 78.14 per cent. in the former, and 86 per cent. in the latter.

27. In the inoperable cases, the nontobacco users reached as high as 30.76 per cent.

28. The patients who were treated with pastes, plasters, etc., before entering the clinic did not get such good total good results as those who were not so treated; 62.06 per cent. in the former and 77.08 per cent. in the latter; moreover, 31.91 per cent. of the former who were operated on had metastasis, while only 19.48 per cent. of the latter operated on had metastasis.

29. Of the patients with metastasis, 17.39 per cent. are living and 82.6 per cent. are dead.

30. Of the living who had metastasis, 83.33 per cent. report a good result. In these patients the submaxillary lymph nodes on only one side were involved.

31. No patient with the cervical nodes or more than one group of any lymph nodes involved has been reported living.

Fig. 11 (a 38260).—Grade 3 epithelioma of one of the left submaxillary lymph nodes, secondary to epithelioma of the lip; slight differentiation; the patient died from epithelioma five months after the last operation, and twenty months after the onset of the disease: *a*, partially differentiated cells; *b*, undifferentiated cells.

TABLE 17.—RESULTS FOLLOWING OPERATION ACCORDING TO GRADE

	Grade 1	Grade 2	Grade 3	Grade 4
Information received from patients operated on	45 (52.94% of 85)	192 (59.81% of 333)	65 (62.26% of 113)	4 (100% of 4)
Patients living	40 (88.88% of 45)	128 (66.66% of 192)	16 (24.6% of 65)	
Patients living, good result	39 (97.5% of 40)	119 (92.96% of 128)	13 (81.25% of 16)	
Patients living, fair result	1 (2.5% of 40)	8 (6.25% of 128)	2 (12.50% of 16)	
Patients living, poor result		1 (0.78% of 128)	1 (6.25% of 16)	
Patients dead	5 (11.12% of 45)	64 (33.33% of 192)	49 (75.38% of 113)	4 (100% of 4)
Good result	4 (80.00% of 5)	23 (45.09% of 51)	6 (15.78% of 38)	
Fair result	1 (20.00% of 5)			
Poor result		28 (54.90% of 51)	32 (84.21% of 38)	4 (100% of 4)
Not stated		13	11	
Total good result (patient recovered from epithelioma and is living or recovered from epithelioma and died from other cause)	43 (95.55% of 45)	142 (79.32% of 179)	19 (35.18% of 54)	
Total fair result (patient living with slight recurrence or died from other cause)	2 (4.45% of 45)	8 (4.46% of 179)	2 (3.70% of 54)	
Total poor result (patient living with no improvement or died from epithelioma)		29 (16.20% of 179)	33 (61.11% of 54)	4 (100% of 4)
Total result not stated		13	11	

32. Of the patients reported dead who had metastasis, 91.66 per cent. died from epithelioma.

33. If a patient has the submaxillary lymph nodes on one side only involved, he has a 1 to 3 chance of getting a good result, and will be living and well on an average of 6.18 years after operation.

34. Of the patients operated on in whom no metastasis was demonstrated, 76.26 per cent. are living, and 23.73 per cent. are dead; of the living, 92.71 per cent. report a good result.

35. The average duration of the lesion in the patients with metastasis is 3.27 years, as compared with 2.40 years in those without metastasis; the average size of the lesion is 3.74 cm. in the patients with metastasis, as compared with 2.01 cm. in those without metastasis.

36. Among the known causes of death, deaths from epithelioma were as follows: none of Grade 1; 54.90

Fig. 12 (a74162).—Grade 4 epithelioma of the liver secondary to epithelioma of the right side of the upper lip; no differentiation; numerous mitotic figures; high degree of malignancy; the patient died four and one-half months after the last operation, and eleven months after the onset of the disease, with metastatic epithelioma of the lymph nodes of the right side of the neck, right peritracheobronchial nodes, right lung, and liver: a, mitotic figures.

per cent. of Grade 2; 84.21 per cent. of Grade 3, and 100 per cent. of Grade 4.

37. Some malignant neoplasm was associated with the epithelioma of the lip in 0.93 per cent. of the patients.

The First Book on Pediatrics.—The first book ever published on children's diseases is probably the work by Omnibono Ferrarii, printed in Bruges, 1557. The book is in Latin, in quarto, has 196 pages, besides three chapters with 12 pages of aphorisms. The book is dedicated to the College of Physicians and Philosophers of Verona. The dedicatory expresses the view that every person should have two purposes in life: First, avoid laziness so as not to waste his life, and second, show his gratitude to the persons from whom he has received any favors. According to the author, his book was written after having noticed that the ancient physicians who wrote about children did not say anything about nurses' diseases nor describe methodically the different diseases that might befall children.

THE INTESTINAL TUBE

ITS SIGNIFICANCE AND APPLICATIONS*

JACOB BUCKSTEIN, B.S., M.D.

First Lieutenant, M. C., U. S. Army

FOX HILLS, STATEN ISLAND, N. Y.

In the descriptions contained in this article, I am dealing primarily with the introduction of the rubber tube into the intestine beyond the duodenum. I have therefore taken the liberty of referring to it as an intestinal tube, rather than a duodenal tube, for the latter might imply that its use is limited to the duodenum.

The primary purpose of this study of a series of roentgenograms of the intestinal tube in a given case is to demonstrate more clearly the principle of the detachable bulb, as outlined in a preceding communication.¹ In that article, I described a modification of the duodenal tube, which, I believe, enhances its usefulness in intestinal feeding. In the first place, several openings were made along the course of the tube, up to a distance of about 1½ inches from its end, each opening about the size of its lumen. The purpose of this was to minimize the possibility of occlusion which occasionally occurs. Of greater value was the change from an end-piece that was permanently attached during its sojourn in the intestine, to an end-piece that could be detached shortly after the tube had reached its destination. This modification was considered of importance because of the possibilities of danger resulting from a prolonged direct contact of a weighted substance with the delicate intestinal mucous membrane. The detachable bulb not only obviates this factor, but as a direct result, makes it possible to use the tube in the intestine over a longer period of time, a factor which might be of value in the more chronic affections. I was able to accomplish this modification by sewing the metallic bulb to the end of the rubber tube with catgut. Plain catgut was first used, but in a number of cases, owing probably to a contraction of the pyloric sphincter, the tube remained in the stomach for several hours and the gastric secretions had digested the catgut, causing the premature detachment of the bulb. Without a weight at the end of the tube, there was a tendency for it to remain coiled within the stomach, the end failing to pass into the intestine. After experimenting with different kinds of catgut, I decided on the use of chromicized catgut No. 4, as this gave the most satisfactory results.

To illustrate this principle more clearly, it was decided to take a series of roentgenograms from the time the tube was swallowed and the end had passed within the intestine, until the bulb had left the intestinal canal.

As soon as the clear bile colored fluid was obtained by aspiration, I had a roentgenogram taken, with the result shown in Figure 1. The roentgenogram was taken during the process of injecting a suspension of barium in buttermilk through the open end of the tube by means of a syringe. The picture obtained showed the end of the tube within the intestine. From then on, roentgenograms were taken at varying intervals, with the idea of obtaining information regarding the time when the detachment of the bulb from the end of the tube occurred; and finally, after the bulb had left

* From the Medical Service, U. S. Army General Hospital No. 41, Col. C. R. Snyder, Chief of Staff.

1. Buckstein, Jacob: Experiences with Duodenal Feeding at U. S. Army General Hospital No. 41, J. A. M. A. 73: 670 (Aug. 30) 1919.

the intestinal canal and had been recovered from the stool, a roentgenogram was obtained showing only the rubber tube in place.

This detachment of the bulb is clearly demonstrated in Figure 2. The last plate of this series (Fig. 3) was taken after the bulb had been recovered from the

the taking of the roentgenograms, the patients engaged in the ordinary motions of getting off the roentgen-ray table, walking, sitting down and arising, getting back on the table at the appointed time, and movements of a similar nature. In the different pictures of each series I noticed changes in outline, no two being alike

Fig. 1.—Shortly after the removal of intestinal fluid.

Fig. 2.—Thirty-two hours after swallowing the tube; bulb (indicated by arrow) detached.

Fig. 3.—Fifty hours after swallowing the tube, and shortly after recovering the bulb from the stool.

stool. As a rule, the bulb is recoverable from thirty-six hours to four days after the tube is swallowed. In one case, although the bulb became detached within thirty-six hours, the patient did not recover the bulb from the stool until the fortieth day.

In examining the series of plates, I noticed an interesting fact: In the same patient and with the same length of tubing the outline of the intestine was different in each succeeding picture, although at the time each roentgenogram was taken, the patient occupied the same prone position. To demonstrate this change more

although taken with the same length of tube in the same patient and in the prone position.

The series of pictures appeared to indicate what may perhaps best be referred to as a shifting motion of the intestinal coils. It would seem, on *a priori* grounds, that such a shifting motion must inevitably be expected when we realize that the many coils of intestine attached to the mesentery are freely movable within the abdominal cavity. As the tube outlines the intestine, any change in position of the intestine will be indicated by a concomitant change in the position of the tube.

Fig. 4.—Tube swallowed for a distance of 120 cm. from the teeth.

Fig. 5.—Roentgenogram taken one hour after swallowing the tube.

Fig. 6.—Two hours after swallowing the tube.

clearly I had another patient swallow the rubber tube for a distance of 120 cm. from the teeth. Roentgenograms were taken at varying intervals, as indicated in Figures 4, 5 and 6. Another series (Figs. 7, 8, 9 and 10) was taken at a distance of 130 cm. from the teeth, and still another series (Figs. 11 and 12) at a distance of 150 cm. from the teeth. In the intervals between

To determine whether changes in the outline of the coils occurred while the patient continued in the prone position and did not move about between the taking of the roentgenograms, a series of plates was taken while the patient remained prone during the entire period. One picture was taken every five minutes during the course of one hour. On examination, practically no

change in intestinal outline was visible in the different plates.

We may assume that the changes in outline in the various series were due to changes in the position of the body in the intervals between the taking of the pictures. We may conclude, first, that a roentgenogram

the shifting motion of the intestinal coils, clearly indicated in the illustrations, probably plays a real part in the mechanical process of propulsion.

The possibility of the introduction of the end of the rubber tube to different portions of the small intestine widens the field of gastro-enterology from a practical

Fig. 7.—Tube swallowed for a distance of 130 cm. from the teeth.

Fig. 8.—Five minutes after swallowing the tube.

Fig. 9.—Fifteen minutes after swallowing the tube.

of a rubber tube within the intestine gives us an indication of the outline of the intestine only at that particular time; secondly, that there is a continual change in the position of the intestinal coils brought about through bodily motion, and thirdly, that we have here an indication of one specific way in which exercise acts as a therapeutic measure in some cases of chronic constipation.

It is a plausible assumption that the movement of the intestinal coils will be increased as the result of the increased bodily motion. A marked increase in the shifting of the intestinal coils probably aids in the

therapeutic standpoint, and also from the standpoint of the biochemistry, bacteriology and parasitology of the intestinal canal. Since the end of the tube may pass well within the intestinal canal, the principle of duodenal feeding may be extended in its application to intestinal feeding, which may perhaps find a use in the rare conditions of jejunal and gastrojejunal ulcers that may complicate a gastro-enterostomy, and perhaps also in the case of fistulas that might conceivably occur at different parts of the intestine.

The principle of transduodenal lavage was first emphasized by Jutte. While our ordinary enemas at

Fig. 10.—Two hours after swallowing the tube.

Fig. 11.—Tube swallowed for a distance of 130 cm. from the teeth.

Fig. 12.—Twenty-four hours after swallowing the tube.

onward propulsion of material contained within the lumen. For this reason, apart from its value in toning up the entire system through its influence on the circulation, exercise is to be advocated where constipation occurs in those of sedentary habits.

While rhythmic segmentation and intestinal peristalsis are the prime factors in the mechanics of digestion,

best reach only a small portion of the intestinal canal, we have by means of lavage through the intestinal tube a method of cleansing the entire intestinal canal and ridding it of stagnating material. Oxygen insufflation, and the introduction of medication through the tube, have also been practiced. Not only may lavage and medication be employed in this way, but the ready

passage of the tube to varying distances within the lumen of the intestine makes possible the direct introduction of therapeutic agents to definite parts along the course of the intestinal tract.

Of interest from a biochemical standpoint is the fact that we may obtain intestinal secretions for examination. Hitherto, our analysis of the gastro-intestinal secretions in the living human being has been practically limited to the secretions of the stomach and of the duodenum. The value of our results was enhanced through the methods of fractional examination of the gastric secretions as emphasized by Rehfuess, and of the fractional examination of the duodenal secretions emphasized by Einhorn. There is no mechanical difficulty in the way of obtaining secretions beyond the duodenum. I believe that analysis of these secretions may not only prove of theoretical interest, but also may ultimately throw light on some of the more obscure intestinal derangements.

SUMMARY

1. There is a distinct value in the principle of the detachable bulb for the construction of the intestinal tube when used for feeding.
2. The intestine is clearly delineated in a roentgenogram by means of the barium filled rubber tube.
3. The shifting motion of the intestinal coils, as indicated by the changing outline of the rubber tube, throws some light on the mechanics of propulsion and on the therapeutic value of exercise in constipation.
4. Direct introduction of therapeutic agents is made possible at specific portions of the intestine.
5. Secretions from different portions of the intestine below the duodenum may be obtained for the purpose of biochemical, parasitic and bacteriologic examinations.

THE TREATMENT OF ECZEMA*

J. S. EISENSTAEDT, S.B., M.D.

Instructor in Dermatology, Northwestern University Medical School;
Attending Dermatologist, Cook County Hospital

CHICAGO

As is generally well known, many diseased conditions of the skin are classed as eczemas or dermatitides. The so-called trade or occupational eczemas under the newer classification are considered as dermatitides. In discussing the treatment of eczema, therefore, it must be borne in mind that while the disease is a clinical entity, it does not represent a definite pathologic process with well-defined etiology. While it is true that many external factors may precipitate the outbreak of eczema, it is commonly assumed that some peculiar predisposition to the disease exists. This is perhaps a metabolic error, because the same external noxae which bring about an outbreak of eczema in a susceptible person will not provoke the eruption in a normal one. Concerning this point a painstaking and thorough examination of the patient and minute attention to his history and habits are of value.

Changes in metabolism which predispose to eczema are not well understood. At times these inherent causes cannot be determined; at other times they may not be controllable. In all instances in which the internal causative factors are not apparent, or their discovery is delayed, the pathologic process should be

treated as observed. The patient should be warned against contact with irritating substances which may produce inflammation of the skin. If, however, the underlying cause in a given case can be determined, its elimination must be accomplished or at least attempted.

Eczema most frequently affects printers, bakers, painters and plasterers; but washerwomen, janitors, and employees in certain chemical industries or those who constantly come in contact with various irritating substances, are likewise frequently sufferers from this disease. In this type of case the patient will, of course, be ordered to refrain from his work until he is completely cured. Even then, recurrences may be anticipated if the same occupation is followed. These untoward circumstances often make treatment and cure financially difficult for the patient. Such susceptible persons should be advised to change their trade or occupation if possible, so that recurrences may be avoided.

The treatment here described has been found safe and in the majority of cases satisfactory in my own work. The external treatment of eczema depends on the intensity, the stage of the disease, and its duration; in other words, on the clinical symptoms as interpreted from a pathologic point of view. Those substances

Fig. 1.—Eczema of the face with crusts and scales and papules at borders of the lesions.

which produce irritation of the skin should first be eliminated from the patient's surroundings. In severe and generalized or extensive cases the patient should not wear starched linen or other articles of dress which rub against the inflamed parts. He should be confined to his room and should not exert himself, so as not to become overheated and thus produce hyperemia, which

aggravates the condition. Next, the skin should be treated with preparations which tend to alleviate the itching and to cause the inflammatory process to retrograde. There is no specific medication for the disease: each case requires therapy based on the clinical picture at the time the patient comes under treatment. The physician should not change too rapidly from one type of medication to another. If a given preparation or combination causes improvement, it should be continued until improvement ceases. Nothing is so fruitless, nothing causes more harm, than irrational, ever-changing therapeutics.

ACUTE ECZEMA

In acute papular or papulovesicular eczema the skin is often so irritable that salves and ointments as well as pastes are poorly tolerated. In these instances applications of a mild alcoholic solution of 0.5 per cent. of salicylic acid followed by the use of a bland dusting powder are indicated every three or four hours.

The alcoholic solution of salicylic acid has a slightly astringent action as well as a cooling effect, and the dusting powder affords desirable protection. In this way the eczematous outbreak can often be aborted and recovery obtained in a few days. On the other hand, the papules may prove resistant and while the associated erythema and swelling disappear, the papules become somewhat harder in consistency and

roofs of the vesicles. Impermeable substances, such as oil silk or gutta percha tissue should not be applied over these wet dressings. It is distinctly desirable, however, to change dressings frequently. Dressings saturated with any of a number of solutions meet the indications admirably. Lead water diluted with from five to eight parts of water, solution of aluminum subacetate diluted with nine parts of water, and an aqueous solution of ichthyol 1:100, have proved efficacious.

These solutions are best used cold and should be changed every ten or fifteen minutes. The gauze should not be folded in more than three or four thicknesses, so that evaporation can readily take place. In the event that aqueous solutions are poorly tolerated, a mild ointment, such as boric acid and benzoated lard, or a mixture of equal parts of lime water and olive oil may be tried.

Should there be only slight or no improvement from these aqueous solutions or mild ointments, it is advisable to resort to the use of ointments or pastes of greater consistency; for example, zinc oxid ointment, or Lassar's paste, applying the ointment on linen or mull bandage and swathing the part. If, finally, even the thicker ointments and pastes do not bring results, it may be necessary to resort to energetic stimulation which causes a crust to form. The crust acts as a protective covering under which the repair process goes forward. Stimulating applications may be made by painting the part with a 5 per cent. silver nitrate solution, or with a 10 per cent. alcoholic solution of tar. After application the part is covered with starch powder. It is well again to emphasize that the medication which causes improvement should be continued, while that which aggravates the condition or which

Fig. 2.—Marked subacute eczema of the right arm, with scales and crusts and papules at border of patch.

more apparent to the eye. At this stage the skin is not so irritable and may well tolerate ointments and pastes, followed by the application of a bland dusting powder, or a zinc oxid lotion may be used.

	Gm. or C.c.
Zinc oxid	15
Starch	
Glycerin	
Distilled water	15
Label: Zinc oxid lotion.	

Under this treatment, the acute cases become subacute, the papules lose their redness, and become darker or somewhat livid or brownish in hue. At this point a high dilution of some drug which hastens desquamation may be added to the ointment or paste. For example, tar preparations, such as the oil of cade or rectified oil of birch tar, ichthyol and its allied preparations, or salicylic acid, may be added.

	Gm. or C.c.
Zinc oxid	10
Talcum	20
Petrolatum	
Rectified oil of birch tar	3
Label: Tar-zinc paste.	

The use of tar preparations is indicated especially at this stage because of their effect in controlling dilatation of the blood vessels. However, it must be emphasized that their use should be followed rather gingerly, testing out, as it were, the patient's tolerance. It is not well to prescribe oil of cade or oil of Russian birch in strengths greater than from 0.5 to 1 per cent. in the first prescription containing tar.

In cases of vesicular and moist or weeping eczema the skin is in an even more irritable and intolerant condition. Here only the blandest, most soothing and cooling applications may be used. The preparations first mentioned are not to be used. Alcohol would cause pain, and dusting powders in admixture with the serous exudate would form a thick, adherent crust. One must, therefore, select applications which are protective and which at the same time will permit the free evacuation of the products of inflammation. In this instance a moist or wet dressing has cooling qualities and at the same time aids in the maceration of the

Fig. 3.—Eczema squamosum et crustosum of the leg with thickening of the skin, accumulation of scales and crusts and relatively sharp demarcation of lower margin of patch.

brings about no improvement must be immediately stopped.

In more chronic cases of vesicular eczema when the acute inflammatory symptoms have disappeared and when oozing has stopped and the patches are covered with adherent crusts (eczema crustosum), a good local application is a dressing impregnated with an astringent.

gent paste or ointment. Diachylon ointment serves this purpose very well; the ointment is applied to linen and the bandages are changed once daily and the part cleansed with olive oil. Such dressings are continued until all evidence of the disease has disappeared.

ECZEMA SQUAMOSUM

The method just described is applicable to cases of squamous eczema without previous use of the foregoing methods of treatment, because it will cause maceration of the scaly covering of the patch and produce an astringent effect on the dilated vessels. It also serves as a valuable protective covering. The standard treatment for squamous eczema is the application of nonirritating ointments or pastes to which may be added some antipruritic, such as thymol, phenol, camphor or salicylic acid. Tar preparations are indicated when the area has become distinctly less inflammatory and has taken on a bluish red or livid appearance. When the patient is free from eczema he must observe certain precautions: He must use a minimum of water on the skin; he should use only nonirritating soaps, and following a bath he should anoint his body with a bland oil.

ECZEMA OF THE SCALP

Eczema of the scalp is considered a special type of the disease because the numerous sebaceous glands partake in the inflammatory reaction. Thick pastes or ointments are naturally not indicated and must not be used. Nightly applications of oil to the scalp with a protective dressing on the head are advised, the scalp to be washed with soap and warm water in the morning. In this way the crusts and other products of inflammation are removed. The removal of crusts is essential so that subsequent therapy may reach the affected integument. In cases of moist eczema of the scalp, applications saturated with solution of lead acetate or aluminum subacetate meet the indications. When the oozing or weeping has stopped it is well to apply oily suspensions or thin ointments containing tar, sulphur or both.

	Gm. or C.c.
Rectified oil of birch tar.....	1
Precipitated sulphur	2
Benzoated lard	20
Petrolatum	20

Label: Apply to scalp.

To remove the scales an alcoholic lotion may be used with a small admixture of kerosene or ether. In many cases of chronic eczema of the scalp a 5 per cent. white precipitate ointment is of great value.

ECZEMA OF THE NARES

This condition is frequently associated with pathology in the nasal cavities, for example, deflected septum, hypertrophied turbinates, or polypus, and is often present in cases of chronic rhinitis. In these cases it is well to have the cooperation of a rhinologist. The patient often develops rhagades, and frequently erysipelas may follow if this condition persists. These cases are best treated with tampons impregnated with a 5 per cent. white precipitate ointment or a 10 per cent. ichthyol ointment.

ECZEMA OF THE PALMS

Eczema of the palms and soles is given special consideration because of the marked thickness of the

epidermis in these parts. The vesicular type is rarely seen here because the epidermis is so closely and intimately connected with the underlying structures. In these cases a marked thickening of the epidermis is noted. The first therapeutic indication is the removal of this horny accumulation, so that the underlying inflammatory process may be influenced by the medication ordered. This can be accomplished by energetic therapy which produces maceration, for which a suitable ointment applied to a mull bandage and brought into intimate apposition with the skin is very useful.

Diachylon ointment	Gm. or C.c.
Oil of cade.....	30
Label: Apply on linen and bandage.	6

During and after this mode of treatment it is well to use a formaldehyd ointment, because of the marked hyperhidrosis which is frequently associated with this form of eczema.

Solution of formaldehyd.....	Gm. or C.c.
Menthol	5

Petrolatum	25
Label: Formaldehyd ointment	

Fig. 4.—Chronic eczema of left leg associated with varicose veins, horny epidermis, scales and hard infiltrated papules at margin of lesion.

The frequent use of water is not permitted because it stimulates the growth of horny epidermis.

ECZEMA OF THE BREAST

In eczema of the breast it is well to examine the patient carefully for the presence of scabies. If scabies exists it should be energetically treated regardless of the intensity of the eczema. If the eczema is a result of nursing and the condition is not so severe as to necessitate weaning the child, great care must be exercised not to prescribe drugs which might be toxic to the infant. With these reservations, eczema of the breast is treated according to the foregoing rules and suggestions.

ECZEMA OF THE GENITAL AND ANAL REGIONS

It is not unusual to find eczema around the genital and anal regions, since hemorrhoids and constipation favor its presence. Cases of nervous pruritus ani are frequently sources of eczema, owing to the rubbing and scratching of the parts by the patient. Close attention to the regularity of the bowels, scrupulous cleanliness locally, and the use of ichthyol rectal suppositories are important aids in the treatment of the condition. In this location also, as long as there is weeping, applications of solution of aluminum subacetate are indicated, after which stage mild ointments may be used.

However, in many cases of eczema around the anal region, tar and other stimulating drugs may be used earlier than elsewhere.

The skin must be kept as dry as possible because any excess of moisture causes untoward maceration. In order to avoid this, ample dusting with starch powder and the application of a suspensory padded with absorbent cotton are valuable. To allay itching in the anal region, many drugs may be used in various types of application. However, one often has to experiment with the individual case to determine which drug to employ. The following may be used alone or in combination: tar, salicylic acid, betanaphthol, compound sulphur ointment (Wilkinson's ointment), solution of coal-tar, and ichthyol.

ECZEMA IN CHILDREN

In eczema of children one proceeds ordinarily in the routine manner. The children are not bathed, the skin is anointed with olive oil, and very mild ointments, such as zinc oxid ointment or zinc oxid ointment mixed with diachylon ointment, are applied to the skin. In order to prevent scratching, the hands of the child are tied. Later, as the condition improves, it is well to wash the skin with 40 per cent. alcohol.

In those locations where the skin surfaces lie in contact with one another, intertrigo often occurs in children as well as in adults. In order to care properly for these cases it is necessary to cleanse the skin carefully and to keep the surfaces apart by interposed padding. In fat children suffering from eczema intertrigo, one often sees dusting powders liberally used, frequently talcum powder, which forms into granules of variable size and often serves as an additional source of irritation. The principle of applying a bland powder is correct, but the result of using a dusting powder, especially talcum alone, is often unfortunate. Dusting powders may be used advantageously if applied on absorbent cotton rolls which are placed between the folds of the skin. By this method the cotton absorbs the moisture, and the powder does not form into rough, irregular, irritating granules. The cotton rolls must, of course, be changed frequently because they quickly become saturated. Here again in cases of marked or even moderate oozing the indication is for moist dressing of solution of aluminum acetate or subacetate, which should be applied cold and frequently changed.

ECZEMA ASSOCIATED WITH ANEMIA

In cases of eczema associated with marked anemia, the treatment is similar to the same type of eczema in other persons, except that experience has shown that the admixture of cod liver oil in the ointments favors their tolerance. The general condition of the patient,

usually a young person, must, of course, be taken into consideration. Iron, arsenic, cod liver oil or other remedies for anemia may be prescribed as indicated.

CHRONIC ECZEMA

Chronic eczema shows superficial inflammatory signs similar to those noted in the acute type. However, there is present in these cases a deep-seated infiltration of the corium resulting from the protracted course of the disease. Therapy is directed, therefore, first toward the symptoms as observed, and second, to overcome the infiltration in the corium and the thickening of the skin. So long as the latter is not accomplished, recurrences may be expected. The superficial inflammatory reaction is treated in the same manner as in acute or subacute cases, with moist dressings, ointments, pastes and other applications. It usually yields readily to treatment and leaves the skin somewhat discolored, scaly, and often cyanotic and thickened.

In these chronic cases we do not then apply ointments containing tar or ichthyol as has been described,

but institute a definitely planned treatment which compresses the involved cutis, and produces maceration and subsequent exfoliation of the overlying layers. This is best carried out with bandages impregnated with diachylon ointment, which actually function as plasters, or, in less inflammatory cases, by the use of salicylic acid plaster. This treatment must be carried out often for a period of weeks, but eventually produces excellent results.

It is well in cases of marked thickening of the skin to apply a thin coating of the undiluted oil of cade with a camel's hair brush, and then bandage with diachylon ointment. If this intensive therapy is poorly tolerated, the

parts may be bandaged with Lassar's paste after the application of oil of cade. Often such dressings may be left for several days, and need not be removed unless the patient complains of burning or pain. This method simplifies the treatment considerably. The latter part of the treatment of such a persistent chronic case is carried out by the application of tar ointments or pastes, but only after the intense thickening has been carefully eliminated by the previous use of bandages.

INTERNAL THERAPY OF ECZEMA

In an article of this character the internal treatment can only be outlined. As has been stated, the causative factors of internal origin, when discovered, must be eliminated as completely as possible.

The dietary management of a patient is one of the most important features in the treatment of many if not most cases of eczema. Some patients do not tolerate carbohydrates as well as others, and in these cases a reduction of carbohydrate intake almost to complete

Fig. 5.—Chronic eczema with marked lichenification on inner aspect of thigh.

elimination is a necessary procedure. In all cases it is well to examine the urine, noting any change from normal; sugar especially should be looked for. Some cases of carbohydrate intolerance, while showing no sugar in the urine, present quite constantly an increased amount of sugar in the blood.

Other patients are intolerant of sodium chlorid in large quantities, and questioning will often bring out the fact that these patients indulge overmuch in the use of ordinary table salt. Still other patients eat excessive quantities of nitrogenous articles of food, and a diminution in this element is of distinct advantage.

Especially in persons past middle life suffering from eczema, nephritic changes should be looked for, and if present, properly treated. Certain other patients with eczema present an anaphylactoid if not a true anaphylactic reaction against specific proteins or proteins of certain groups, among which may be mentioned egg albumin, pork, and the protein of cow's milk. It would lead too far ahead to enter on a discussion of the various proteins which, in susceptible persons, may cause an outbreak of eczema, but the careful clinician will bear these possibilities in mind and will inquire into the dietary habits of his patients. Often he will find that the patient himself may connect the ingestion of certain articles of diet with the appearance of the eruption. A patient recently under my care reacted in a marked way to the ingestion of walnuts. Besides the eczematous condition which followed he also presented marked edema of the nasal and conjunctival mucosae. It is well, therefore, to start a patient off with an absolutely bland diet, which is readily digestible and which contains little or none of the substances that experience has shown may be productive of eczema.

There are undoubtedly patients in whom the predisposition to eczema can in a greater or less degree be controlled by organotherapy. I have repeatedly seen patients materially aided by small doses of thyroid substance, and several neurotic and underdeveloped young women, I am sure were markedly benefited by the use of corpus luteum extract. However, the physiology and therapeutic uses of the ductless gland substances are in general so poorly understood that it is impossible to give clear-cut indications for their use, and the suggestion is offered merely as one that they may sometimes be helpful in the management of eczema.

25 East Washington Street.

Infant Mortality in War Zone.—A report on the subject of the sufferings of French and Belgian children under German domination in the occupied regions has been made to the French Academy of Medicine by Dr. Albert Calmette. It was found that out of 18,036 children who at the time of the armistice were attending the public or private schools of Lille, rather more than 8,000 had to be sent to hospital or convalescent colonies by the ministry of the invaded regions. This selection, made by specially qualified doctors, established that in all the scholastic groups at the end of the occupation the growth of 60 per cent. of the children had been definitely arrested, while about 40 per cent. showed clear signs of tuberculosis of the lymph glands. In a single school (Ecole Fombelle) inspected in March, 1919, of 210 children examined only one was normal; 163 suffered from deformity or other disease; 139 had swollen glands; forty-two had rickets, and six had pulmonary tuberculosis.—*Med. Officer*, Nov. 29, 1919.

Clinical Notes, Suggestions, and New Instruments

BLOOD TRANSFUSION APPARATUS

L. L. STANLEY, M.D., SAN QUENTIN, CALIF.

This blood transfusion apparatus was devised and has been successfully used at the California State Prison, at San Quentin, Calif. It is of the ball valve plan, and may be used with any capacity Luer syringe.

Fig. 1.—Details of blood transfusion apparatus.

When the plunger of the syringe is drawn out, the ball *A* (Fig. 1) engages in the socket, not permitting any fluid to pass it, while the ball *C* is displaced upward to position *B*, allowing the blood to come from the donor into the syringe. When the syringe piston is pushed in, the ball in the lower chamber engages the socket at *C*, preventing the fluid from returning to the donor. At the same time the ball *A* is released from its socket and assumes a position in the upper chamber at *D*, allowing the blood forced from the syringe to flow into the veins of the recipient.

Fig. 2.—Blood transfusion apparatus and buret.

The donor and the recipient are placed on adjoining tables, with the arm of the recipient slightly higher than that of the donor, for the balls engage by gravity, and the valve must be held in a vertical position. The syringe is thoroughly sterilized, and the inside is coated with Abiemann's citrated ointment, which consists of:

	Gm. or C.c.
Adeps lanae	10
Aqua	10
Sodium citrate	10
Petrolatum	10
.....q. s. ad	100

The valve connections and needles are boiled together.

With the syringe connected, enough physiologic sodium chlorid solution is drawn in to displace any air, and leave a

few cubic centimeters in the barrel. The cubital veins of both parties are located, and tourniquets applied. The needle is placed first into the vein of the donor, and when blood begins to flow, is connected to the apparatus at *E*. Similar procedure is done with the recipient, and when the connection is made at *F*, the operator may pump the blood.

The apparatus is so arranged that it may be taken apart and thoroughly cleaned. It is well to have two of these valves, one to quickly replace the other, in case the syringe should begin to work hard, or the blood begin to clot. The first valve is easily disconnected at *E*, *F* and *G*, and the second one substituted.

Should it be desirable to give citrate solution with the blood, a buret (*I*, Fig. 2), to which is attached a rubber tubing with a No. 28 hypodermic needle at the end, is provided. When the apparatus is connected up, the needle is plunged into the connecting tube at *H*. As the blood is drawn in from the donor, likewise the citrate solution is taken in from the container *I*. The percentage of the mixture is regulated by the size of the needles at *H* and *E*, and the strength of the citrate solution.

The advantages of the apparatus are:

1. The amount of blood transfused can be measured.
2. The blood is not exposed to the air.
3. The method is direct.
4. Only veins are used, and repeated transfusions from the same donor may be made.
5. Any amount can be transfused, and done very quickly.

In this prison, many injections of arsphenamin are given each week. When the patients are ready, sufficient solution is prepared for ten consecutive injections.

With this apparatus, using a 50 c.c. Luer syringe, one dose is drawn from the mixing vessel through the donor's tube, and injected into the patient, through the recipient's tube. This is more satisfactory than the gravity method, and saves considerable time.

UNIQUE FOREIGN BODY IN NOSE*

IRVING WILSON VOORHEES, M.S., M.D., NEW YORK

N. A. W., a colored man, aged 34, a native of the British West Indies, came to the West Side Dispensary, Jan. 17, 1920, with a history of yellow discharge from the right nostril during the previous two months. Examination revealed a large black mass in the right nasal fossa, very firm and hard, but freely movable in its bed. The septum was pushed over to the left, and the mass was bathed in yellow pus. It seemed reasonable to suppose that we had to do with a mass of necrotic bone, probably a sequestrum from the naso-antral wall following a tertiary lesion. Pledgets of cotton saturated with 10 per cent. cocain were introduced into the nose and left for ten minutes, at the end of which time our diagnostic acumen received a rude shock.

When 17 years of age, the patient tried to invent a gun. He took a piece of bicycle pipe about 1 foot long, into the open end of which he screwed a threaded bolt borrowed for the occasion from some part of a bedstead. He then bored a touch-hole in front of this breech plug. Into the muzzle he loaded a charge of gunpowder, rammed it down, followed this with a few BB shots, which were also rammed down, and then invited his cousin to apply a flame to the touch-hole while he held the apparatus in the position of aiming. The charge exploded and so did the piece of pipe. The breech plug blew backward and had never been seen or found, but small pieces of iron penetrated the left side of the nose in the region of the ethmoid. The scar from these fragments is still quite visible but insignificant. The boy was in bed for seventeen days, and was visited twice daily by a physician, who did not, however, locate the piece of iron. For seven months thereafter the boy experienced pain in his head and between the eyes about 10 o'clock each morning. Considerable discharge came from his nose. This was worse, he thinks, in summer. He came to the clinic chiefly because his friends chided him about a stench from his head, and because of "frequent colds."

*Patient and specimen presented before the Nose and Throat Section, New York Academy of Medicine, Jan. 21, 1920.

After removal of the cocain pledgets, the black mass above mentioned was grasped with strong nasal grasping forceps, and much to our surprise a solid heavy object was gradually withdrawn from the nose, occasioning only slight discomfort in its passage. When washed off under the water tap, the improvised "breech plug" was identified as the missing iron bolt which seventeen years previously had been suddenly projected into the patient's nose.

The dimensions and weight of the bolt were: length 5.5 cm. (2¼ inches); diameter, 1.5 cm. (½ inch); weight, a little over 1 ounce.

There is probably some latent sinus trouble, which we intend to look into as soon as roentgenograms can be made.

It seems hardly possible that any human being could carry such a foreign body in any part of his anatomy for seventeen years and not be conscious of its presence.

Special Article

TYPHOID IN THE LARGE CITIES OF THE UNITED STATES IN 1919

EIGHTH ANNUAL REPORT

THE JOURNAL presents its eighth annual survey¹ of typhoid fever mortality in cities in the United States having more than 100,000 population. The cities included in the summary number sixty, and are the same as those reported on last year.²

It should be especially noted that the calculated typhoid rates for 1919 presented in this report are based on relatively unsatisfactory population estimates. It is now nine years since the 1910 census, and probably in a number of instances the population estimates are quite wide of the mark. The U. S. Census Bureau makes no estimate at all for the population of Denver, Memphis, Portland, Ore., Seattle and Spokane. Special methods of estimation have been used by the Census Bureau for the population of Cleveland and Washington.

The margin of error is probably not great in a few cities, such as Albany, N. Y., but in many others it will doubtless be shown by the 1920 census enumeration that calculated death rates for 1919 will have to be considerably revised. For these reasons, typhoid death rates can be subjected only to a broadly critical comparison this year.

The nine largest cities in the country (Group 1) show a very notable improvement in typhoid death rates as compared with 1918. For the first time, all the cities in this group have a rate below 10. In only one instance (Philadelphia) are the 1919 figures higher than those for the preceding year. Baltimore has the lowest typhoid rate in its history, and rises into the first rank (cities having a death rate of less than 10). The improvement in Baltimore is all the more noteworthy in that the recently annexed territory has had a much higher typhoid morbidity than the older portion of the city. It is stated that for the first

1. The preceding articles were published, May 31, 1913, p. 1702; May 9, 1914, p. 1473; April 17, 1915, p. 1322; April 22, 1916, p. 1305; March 17, 1917, p. 845; March 16, 1918, p. 777, and April 5, 1919, p. 997.

2. The number of typhoid deaths has been sent us by the local officer of health, and the rates have been calculated on the basis of population estimates made according to the method of the U. S. Census Bureau. It may perhaps be noted that the figures kindly furnished us by the municipal officials include the deaths of nonresidents as well as residents occurring within the city limits. In some instances this undoubtedly gives an exaggerated impression of the amount of typhoid fever in a community, but at present statisticians are agreed that "the attempt to eliminate the deaths of nonresidents would often result in an understatement of the true mortality" (Bureau of the Census, Mortality Statistics, 1912, p. 13).

six months of 1919 the morbidity rate in the annexed district was about five times as great as in the old city. It speaks well for efficient health administration in that city that, in the face of this disadvantage, the total typhoid mortality should show a decrease.

A particularly satisfactory improvement appears in Detroit, causing this city to rank well among other Northern cities for the first time in a number of years. The decline in Detroit's typhoid, which began about 1917, has now brought the death rate to the lowest point in the history of the city. Typhoid cases in Detroit are at present being studied very carefully. A relatively large proportion (about 45 per cent.) is attributed to outside infection. The proportion of contact cases seems to be low as compared with the figures for New York City, only twenty-four out of a total of 281 being attributed to this cause. Swimming and bathing in the polluted river water about the city is considered to be an important factor in the typhoid situation. Not a single case has been traced to milk during the three years 1917, 1918 and 1919.

Chicago, New York, Boston and Cleveland report typhoid rates that are astonishingly low. The improvement due to filtration of the Cleveland water supply is doubtless largely responsible for the lowering of the

TABLE 1.—DEATH RATES FROM TYPHOID IN CITIES OF GROUP 1 (MORE THAN 500,000 POPULATION)

	Deaths from Typhoid per 100,000 Population				
	1919	1918	Average 1916-1919	Average 1911-1915	Average 1906-1910
Chicago.....	1.2	1.4	2.7	8.2	15.8
New York.....	2.0	3.7	3.4	8.0	13.5
Boston.....	2.2	2.5	2.8	8.0	16.0

Pittsburgh.....	6.2	9.8	8.9	15.9	65.0
Baltimore.....	8.9	12.2	13.6	23.7	35.1

rate in that city. Chicago heads the list of cities in this group for the third consecutive year.

As in previous years, the New York City Health Department has printed quarterly the results of its detailed study of each typhoid case. Increasing success seems to mark the work of the department in tracing sources of infection. For the last quarter of 1919 it is reported that the probable mode of infection was determined in 35.7 per cent. of the cases, as against 30 per cent. in the corresponding quarter of 1918. A relatively large proportion of the cases was traced to out of town infection. The majority of the cases traced to their source within the city were due to contact with active cases or chronic carriers. Water-borne and milk-borne typhoid infection seems to have almost disappeared from New York City.

It is doubtful whether there is today any other country in the world in which the nine largest cities could show so low an average typhoid rate as that reached in Group 1 in 1919.

The cities in Group 2 (from 300,000 to 500,000 population) show improvement almost without exception over the 1918 rates. Newark, N. J., and Cincinnati reach very low records, and Seattle maintains its admirably low rate of last year (2.3). The protection of the watershed of the Seattle water supply is receiving special attention from the local health authorities, since it is estimated that the watershed now has a population of from 500 to 600. All of these persons are required to submit themselves to typhoid immunization, and

other methods of controlling conditions on the watershed are being energetically carried out.

Milwaukee continues to maintain its astonishingly low rate of the past few years. The purification of the water supply is still an issue in that city. Chlorination is now being practiced and, as the typhoid death

New Orleans.....	13.7	20.1	20.0	20.9	35.6

rate shows, with eminent success; but it is generally considered that filtration will have to be resorted to eventually. Experiments to determine the applicability of various rapid filtration methods have been conducted during the past year.

New Orleans shows a substantial reduction in its typhoid rate for the first time in about ten years, and Washington records the remarkably low rate of 3.7, which brings it at once into cities of the first rank. The table (Table 2) shows the truly amazing improvement that has occurred in Washington in the past ten years. The typhoid death rate in this city in 1919 was almost exactly one-tenth the average rate for 1906-1910.

Group 3 (from 200,000 to 300,000 population) makes a much better record than in 1918, nearly every city showing a decrease in the typhoid rate. Denver and Columbus appear to have been exceptionally favored. Seven cities report rates under 5, as against four cities in 1918.

Rochester, N. Y., for some reason appears to have about doubled its rate of 1918, although the 1919 rate of 3.8 is by no means alarmingly high. Rumors were current in that city at one time during the summer that a break in the water main had led to the entrance of river water into the system; but this report seems to

Kansas City, Mo.	11.2	13.7	11.3	16.2	35.6

have been unconfirmed by the city health authorities. Louisville, Ky., makes a particularly good showing. It is stated, however, that a few cases of preventable typhoid have occurred in that city due to drinking contaminated spring water in a public park. Milk-borne typhoid was also a factor during the summer, but both city and state health departments acted with commendable promptitude, and the neglect of physicians to

report cases of typhoid in the family of a dairyman was summarily dealt with. The degree of improvement reached in Louisville with its large negro population may be appreciated by comparing the average of 1916-1919 (10.8) with the average for 1906-1910 (52.7). Indianapolis and Columbus, two Northern

TABLE 4.—DEATH RATES FROM TYPHOID IN CITIES OF GROUP 4 (FROM 125,000 TO 200,000 POPULATION)

Memphis, Tenn.	58.4	15.9	32.6	42.5	35.3

cities which, for some years, lagged behind similarly situated communities, seem now to be permanently in the class with other cities having the same climatic and racial characteristics. Kansas City, however, shows relatively little diminution in its typhoid rate, and has, indeed, remained practically stationary for four or five years. The rate for 1919 appears to be slightly higher than that in 1916 and 1917. It seems a favorable time for an intensive investigation of the relatively high prevalence of typhoid fever in that city.

Group 4 (from 125,000 to 200,000 population) includes the city with the highest (Memphis) and that with the lowest (Spokane) 1919 death rate in the whole series of sixty cities included in this summary. Spokane reports that it has not had a single death from typhoid fever, a truly remarkable showing, but one that we may anticipate will be rivaled by other communities in the near future. Cambridge, Mass. (Group 5), reports only two deaths, and Hartford, Conn. (Group 5), only one. Spokane, however, seems to

bear off the honor of being the first American city with more than 100,000 population to have no single death from typhoid fever within its borders during a calendar year.

At the other end of the scale, Memphis has temporarily descended into the depths. In March and April, 1919, Memphis suffered from an old fashioned water-borne epidemic of typhoid due to the serious contam-

ination of the city supply. This unfortunate occurrence has made the Memphis rate the highest among the sixty cities here considered. It is, in fact, the highest typhoid rate recorded in any one of these cities since 1911, when it was Memphis again that had the undeniable distinction of having the highest rate from typhoid fever of any large city in the United States. An encouraging feature of the situation in that city, however, is that, except for the water epidemic in the spring, typhoid seemed well under control, only four deaths being reported for the last four months of 1919.

Richmond, Va., makes a new low record of 3.7, a rate which is probably the lowest ever reached by any Southern city of more than 100,000 population. Not a single death occurred in that city during the first six months of last year. The rate is so low, in fact, that difficulty may well be experienced in living up to it during the next few years. We have had occasion to

comment previously on the admirable health administration in Richmond during the last decade, which has been one of the factors that has made such achievements possible. Two other Southern cities, Atlanta and Birmingham, have also established low typhoid rates which must be regarded as highly creditable in view of the climatic and racial conditions with which these cities have to contend. The Birmingham milk supply has very properly been the subject of special agitation. There is reason to believe that milk-borne infection and fly-borne infection are still relatively important typhoid factors in many Southern cities. It can be fairly predicted that with a good pasteurization ordinance the typhoid in Birmingham will be materially reduced as it has been in other cities where suitable measures for safeguarding milk supplies have been put in force.

Toledo, which in 1916 had a rate of about 23, now records the very low rate of 3.1. Fall River, Scranton, Oakland and Worcester are other cities in which the 1919 typhoid rate was very low.

Group 5 (from 100,000 to 125,000 population) comprises seventeen cities. In all but one of these the typhoid rate was lower in 1919 than in 1918, the exception showing only a trifling change. It is plain that in most of the cities in this group the number of deaths is now so small that a slight fluctuation in rate from year to year has little significance. Many cities now report only one, two, three or four deaths in a year, and not all of these are deaths of residents.

It is probable, as stated earlier in the summary, that population estimates for some cities are quite wide of the mark. This is, perhaps, particularly true of certain cities in this group. Such cities as Bridgeport and Dayton, for example, may find their typhoid rates somewhat reduced when the 1920 census figures become available for use in calculation; but in cities of this size having less than half a dozen typhoid deaths, slight rate changes are of comparatively little significance.

It is evident that the maintenance of a low typhoid rate is not to be taken as a matter of course without the exertion of constant vigilance by the local health authorities. The remarkably successful results reached in this group of cities are due to the unremitting efforts of health officers in safeguarding the public water and milk supplies, in applying proper methods of excreta disposal, and in tracking down typhoid carriers. It must be remembered, too, that many of these communities are surrounded by villages and country districts less scrupulous with regard to typhoid occurrence or less able to cope with it than themselves, so that probably a considerable proportion of city typhoid is due to infection contracted outside the municipal limits.

It is worth noting that the three Southern cities that had the highest typhoid rate in Group 5 in 1918 all show a reduction this year.

The continued lowering of typhoid death rates in American cities is one of the outstanding features of modern sanitary progress. The rate for the whole

1919. Other comparisons might be made, but the tables themselves are sufficiently striking.

The unusually large percentage of typhoid reduction shown in 1919 as compared with preceding years may very well be attributed in part to the immunization in the army camps of a large proportion of the particu-

TABLE 8.—TOTAL AVERAGE TYPHOID DEATH RATE (1910-1919)

1919.....	25,526,186	987

* Three cities are omitted from this summary because data for the full period are not available.

larly susceptible age group. It is plain, too, that the continued safeguarding of water and milk supplies has nearly everywhere reduced typhoid to so low a point that health authorities are enabled to devote more attention to the prevention of contact and carrier cases. Wherever it is possible to investigate promptly and thoroughly the circumstances surrounding the development of each individual case, further spread of the disease is likely to be materially diminished. The outlook is highly encouraging for the practical elimination of typhoid fever.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

BENZOCAINE (See New and Nonofficial Remedies, 1920, p. 33).

Anesthesin-Calco.—A brand of benzocaine complying with the N. N. R. standards.

Manufactured by the Calco Chemical Company, Bound Brook, N. J. No U. S. patent or trademark.

GONOCOCCUS VACCINE (See New and Nonofficial Remedies, 1920, p. 283).

The Gilliland Laboratories, Ambler, Pa.

Gonococcus Vaccine (Polyvalent).—A number of strains of *M. Gonorrhoea Neisser* are used in the preparation of this vaccine; the killed bacteria are suspended in physiological solution of sodium chloride and preserved with 0.25 per cent. three cresols. Marketed in packages of four syringes containing respectively 250, 500, 1,000 and 2,000 million killed gonococci; also in packages of four 1 Cc. ampules containing respectively 250, 500, 1,000 and 2,000 million killed gonococci.

OVARY (See New and Nonofficial Remedies, 1920, p. 201).

Ovarian Residue-Hollister-Wilson.—The residue from the fresh ovaries of the hog after the ablation of the corpus luteum.

Actions and Uses.—Ovarian Residue is used for the same conditions as the entire ovarian substance but is claimed to have the advantage of being somewhat more stable in composition (see general article on Ovary, New and Nonofficial Remedies, 1920).

Dosage.—From 0.06 to 0.2 Gm. (1 to 3 grains).

Manufactured by the Hollister-Wilson Laboratories, Chicago. No U. S. patent or trademark.

Ovarian Residue-Hollister-Wilson is a grayish powder, having a peculiar odor. It is prepared from the entire fresh hog ovary by removal by hand of the corpus luteum. The residue is dried and powdered.

TABLE 7.—AVERAGE DEATHS FROM TYPHOID PER HUNDRED THOUSAND IN EACH GROUP, 1916, 1917, 1918 AND 1919

Group	Year	No. of Cities	Total Population	No. of Deaths	Av. Deaths per 100,000
1	1916	9	13,743,746	854	6.2
1	1917	9	14,027,263	774	5.5
1	1918	9	13,869,901	598	4.3
1	1919	9	15,019,516	463	3.1
2	1916	16	4,053,581	344	8.5
2	1917	10	4,150,099	329	7.9

Total....	1919	60	27,028,359	1,126	4.2

group of sixty cities containing approximately one fourth of the population of the country is now less than 5. In 1912, only one of these cities had a rate lower than 5. So late as 1916 there were only three cities with a rate of 2 or less. There are now eight. In 1912 there were only fifteen out of the fifty-one cities then on our list that had a rate less than 10. All but four of these cities had a lower rate than 10 in

AN INDEX OF THE BODY'S MUSCULATURE

The physiologic significance of creatinin, which regularly appears in the urine, is still shrouded in mystery. Its close chemical similarity to creatin, long ago discovered to be a characteristic component of the muscular tissues of the higher animals, has inevitably led to conjectures regarding a relationship between the two chemical compounds; but no tenable theory can be formulated at the present day. The demonstration that urinary creatinin may have a purely endogenous origin and be excreted in comparatively constant daily amounts by persons who do not ingest either creatin or creatinin gave an impetus to the search for its precursor.

The average amount of creatinin excreted daily during a creatin and creatinin free regimen, expressed as milligrams per kilogram of body weight, has been termed the creatinin coefficient.¹ This has been estimated at about 25 mg. for lean persons and 20 mg. for the corpulent, the difference indicating that muscular mass rather than body weight per se is a determining factor in the creatinin coefficient of the body.

Creatinin does not seem to be increased appreciably in the urine as the direct result of exercise; hence it is doubtful whether muscular contraction leads immediately to a transformation of muscle creatin or whether there is some other muscular genesis of the urinary end-product. Nevertheless, it has long been maintained that the creatinin coefficient may be an index of the functional capacity of the muscles, because of its apparent proportionality to the mass of active contractile tissues. In muscular atrophies, the creatinin excretion appears to be below normal.

There are times when body weight gives a distorted view of the functional efficiency of the organism. In such circumstances it would be helpful to have an index as to the degree of involvement of the master tissues of the body. By a suitable indication, the degree of deterioration or restoration might be more accurately evaluated through chemical analysis of metabolism than through physical measurements or clinical inspection. Bürger has reverted to the prob-

lem of the creatinin coefficient by new observations in Schittenhelm's clinic at Kiel.² Numerous determinations on patients there have confirmed the belief that a high coefficient corresponds as a rule with the presence of a vigorous musculature, lower figures being obtained when the muscular development is poor and activity weakened. The original figures recorded by the pioneer American investigators of this subject have been confirmed.

There is a practical value attached to the demonstration that the creatinin coefficient is an index of the extent of participation of musculature in the entire body mass under normal physiologic conditions. When "reduction treatments" are instituted on obese patients, it is not always easy to decide whether the consequent loss of weight is due to combustion of fat or to an undesired disintegration of other than adipose tissues. The determination of the creatinin coefficient may give a much desired clue. With properly conducted therapy to overcome obesity, the coefficient should increase. A calculation shows that on the basis of the conceptions here discussed, 1 gm. of urinary creatinin per day is correlated with about 23 kg. (50 pounds) of muscle tissue. From such statistics it is possible to estimate the approximate muscle content of the body. For the average normal person it should correspond to about 40 per cent. of the body weight. Deductions and applications of the tentative principles here presented are obvious.

DELEGATES TO THE UNITED STATES PHARMACOPEIAL CONVENTION

Attention was called in the General News department of THE JOURNAL last week to the meeting of the U. S. Pharmacopeial Convention to be held in Washington in May. The objects of this convention are set forth in its articles of incorporation:

The particular objects and business of this association are the encouragement and promotion of the science and art of medicine and pharmacy by selecting by research and experiment and other proper methods and by naming *such materials as may be properly used as medicines and drugs with formulas for their preparation* [italics ours.—ED.]; by establishing one uniform standard and guide for the use of those engaged in the practice of medicine and pharmacy in the United States whereby the identity, strength and purity of all such medicines and drugs may be accurately determined, and for other like and similar purposes.

Of primary importance among the functions of the convention, then, are the naming of drugs which may properly be used as medicines; devising of formulas in accordance with which they are to be compounded, and establishing of standards by which their identity and purity may be proved. As this is a large task, requiring special knowledge, the convention properly delegates this work to a body of fifty experts called the "Committee of Revision of the U. S. Pharmacopeia."

1. Shaffer, P. A.: Am. J. Physiol. 28:1, 1908.

2. Bürger, M.: Beiträge zum Kreatininstoffwechsel, I. Die Bedeutung des Kreatininkoeffizienten für die quantitative Bewertung der Muskulatur als Körpergewichtskomponente, Ztschr. f. d. ges. exper. Med. 9: 262 (Oct.) 1919.

Who are best qualified, first of all, to name the drugs which may properly be used as medicines? Obviously, physicians who use drugs in the treatment of disease, and pharmacologists who study the actions of drugs on the living organism. Pharmacists who devise the formulas for compounding drugs or for making preparations for administering such drugs, chemists who establish the standards by which their identity and purity may be determined, and manufacturers whose opinion must be influenced by commercial considerations, should by no means have the deciding vote in this matter.

At the time of the previous revision, a "Committee on Scope" was appointed, to which were referred all questions of additions to and deletions from the Pharmacopeia. The decisions of this committee were to be based on the "therapeutic usefulness" or the "pharmaceutic necessity" of the drugs considered. A majority of the committee consisted of physicians. After a vast amount of work, the Committee on Scope submitted its report, recommending the deletion of a large number of substances which were not considered to be "therapeutically useful" or "pharmaceutically necessary." However, the executive committee (only two members of which may be said to represent those practicing medicine) disregarded the recommendations of the Committee on Scope in many respects, and included or rejected whatever substances it pleased, even including some drugs which had not even been considered by the Committee on Scope. Naturally, the Pharmacopeia thus compiled is an expression of pharmacy and the drug trade rather than of medicine.

To avoid a repetition of these conditions in the next Pharmacopeia, it is essential that each medical organization entitled to representation at the coming meeting of the convention should elect three delegates and three alternates, so that full representation of medical science shall be guaranteed. Delegates should be selected who know what are the interests of scientific medicine in the Pharmacopeia—delegates who realize that physicians, more than any others, are vitally interested in the content of the Pharmacopeia—delegates whose practice and teaching reflect the modern trend to eliminate the unimportant and useless drugs from the Pharmacopeia. The delegates should feel their responsibility and attend and take part in all of the meetings of the convention in order to secure the necessary reforms. It would be desirable that the convention pass a resolution which would make the composition of the Committee on Scope subject to the will of the whole convention. Obviously it is desirable that pharmacologists and physicians should comprise at least the majority of the members of the Committee on Scope, and that the decisions of this committee should be final and not subject to revision by any other committee, general or special. Particularly, its action should not be revised by any committee on which manufacturing pharmacists predominate.

ORAL SEPSIS AND THE ELECTIVE LOCALIZATION OF BACTERIA

Six years have elapsed since Billings¹ published the extensive clinical observations made by himself and his co-workers to demonstrate the importance of septic foci, even when small, as sources of chronic infection conveyed by the blood stream. It was shown that these foci may harbor the same type of bacteria as are found in distant lesions, and that specific types tend to localize in definite organs or tissues. Rosenow,² in particular, has been most energetic in the attempt to demonstrate conclusively the elective localizing power of freshly isolated streptococci found in the focus or systemic lesions of a number of diseases, including appendicitis, ulcer of the stomach, chronic endocarditis, and rheumatic fever.

Inevitably the possible relationship between ill health and oral sepsis has come into prominence in connection with the recent studies on what has lately been termed focal infection. To many it has seemed of late as if tonsillectomy and extraction of the teeth were vying with each other in popularity as procedures for removing objectionable bacterial foci. Rosenow³ has recently applied his methods to a study of the possible significance of dental sepsis. He reports that specific lesions have been produced with bacteria from the various types of dental focal infections, such as gingivitis, pyorrhea, infected pulps, apical abscesses, discharging sinuses, and granulomas. He believes that his newer findings warrant the conclusion that chronic foci of infection about the teeth are potentially or actually detrimental to the health of the persons who harbor them. According to him, the lesions which are more or less enclosed, and which drain only into the circulation, are probably the most dangerous, and that sooner or later, alone or in connection with predisposing factors, they will break down the resistance of the patient and produce disease. Pulpless teeth and blind abscesses are regarded as the most dangerous form of dental sepsis.

In view of the growing favor in which the extraction of teeth is being held, several precautions need to be emphasized. Teeth should never be sacrificed unless the indications for removal are clear. Rosenow avers that tonsillectomy as now so commonly practiced before the condition of the teeth has been corrected is illogical. The lymphatics of the mouth and jaws drain into the tonsils. Some infections of tonsils improve or even disappear following the extraction of infected teeth. The elimination of a visible focus does not

necessarily mean the exclusion of all foci of infection. Vigilance must never be relaxed so long as the results are not all that is expected. When it is at length appreciated that the prevention and cure of dental foci is only one of many factors in the management of infection of obscure origin, the dangers of a one-sided therapeutic point of view will be averted, and a more sane hygiene is likely to ensue. However, the failure of the enthusiasm for oral hygiene to produce a cure-all need not blind us to the helpful contributions which a better knowledge and recognition of oral sepsis have brought to modern practice.⁴

TYPHOID A VANISHING DISEASE

THE JOURNAL's annual summary of typhoid fever in the large cities of the United States,⁵ which appears in this issue, is encouraging beyond expectation. Fifteen years ago, typhoid rates of more than 20 in these cities were very common, and rates of less than 10 correspondingly rare. The most sanguine sanitarian would hardly have anticipated the far reaching improvement that has actually occurred. At that time public health workers believed that any rate under 10 was highly satisfactory, and that a better average than this could hardly be expected for a generation. The author of an excellent work on typhoid, published in 1918, felt himself justified in stating at that time that "we have hitherto been extremely backward in applying recognized methods of sanitary prevention which have long prevailed in other lands." This criticism of American sanitary procedure would perhaps have been justified ten or fifteen years earlier, but long before 1918 the work of typhoid reduction was in full swing. Marked improvement began to occur about 1910, and from that time to this nearly every year has witnessed a fall in the typhoid death rate. The 1919 typhoid rate for a population of about 27,000,000 has reached the exceedingly low point of 4.2.

It should not escape notice that the 1919 rate shows a proportionately large diminution. The most plausible explanation would seem to be that given in our special article, namely, that the antityphoid inoculation of the young men in the military camps has proved a continuing safeguard for this age group, which would ordinarily have furnished a considerable number of typhoid victims. It seems to be evident that water supply and milk supply are hardly important factors at present in typhoid causation in our large American cities.

The great reduction in typhoid cases has everywhere the further advantage that it has now become possible for health authorities to investigate promptly and thoroughly each case of the disease as soon as it

appears. It is thus becoming easier all the time to check incipient epidemics, to discover typhoid carriers, and to exercise better control over the surroundings of each typhoid case. The decrease in the number of typhoid carriers that will come inevitably with the lessening of the prevalence of the disease is sure in the long run to lighten the burden of health officers and to facilitate the task of eliminating typhoid fever. For it must now be recognized that the goal which we may set for ourselves is the practical extinction of typhoid fever in this country. When one city of more than 100,000 inhabitants is able to report not a single death from typhoid, and another city has only one death from this disease, while the city of Chicago, with a population of more than two and a half million, reports only thirty-one typhoid deaths, we are perhaps justified in hoping that the day will come when typhoid, already a medical curiosity in some localities, will become, like smallpox, practically a negligible factor in our mortality returns.

Current Comment

ACUTE RESPIRATORY INFECTION IN MONKEYS FROM INOCULATION OF INFLUENZA BACILLUS

As reported recently in THE JOURNAL, Blake and Cecil¹ obtained interesting results by the inoculation of monkeys with a strain of the influenza bacillus isolated from influenzal pneumonia in a man and subsequently raised in virulence by repeated passages through animals. When inoculated in the nose or nose and mouth there developed an acute, self-limited disease with prostration, fever, cough and sneezing, rhinitis and tracheo-bronchitis, and either leukopenia or no special change in the leukocytes. Purulent sinusitis and hemorrhagic pneumonia developed in some of the animals. On intratracheal injections of the same strain of influenza bacillus, there resulted a similar pneumonia and similar general symptoms. Blake and Cecil regard the disease thus produced as "identical with influenza in man in its course, symptomatology, complications and pathology," and they conclude that "it seems reasonable to infer that *B. influenzae* is the specific cause of influenza." While there is no doubt that the influenza bacillus can cause an infection in the respiratory tract in monkeys that somewhat resembles influenza, it does not seem to have been established that this organism is the cause of influenza. Blake and Cecil recently presented their findings before the New York Academy of Medicine; elsewhere² in this issue is a report of the meeting. In the discussion, exception was taken particularly to the claim that it had been demonstrated that the Pfeiffer bacillus was the cause of epidemic influenza. Dr. William H. Park pointed out that the Pfeiffer bacillus has been found in virtually every case of whooping cough, in 90 per cent. of measles cases, and also in a large

percentage of cases of respiratory infections which had been examined. It was his belief that the experience of Cecil and Blake had been important in designating that lesions can be formed in monkeys by the Pfeiffer bacillus similar to those found in the pneumonias occurring in influenza. According to Dr. Zinsser, the work had made it seem somewhat more likely that the influenza bacillus is the etiologic factor; and yet he did not believe that final judgment can be given on this point. The evidence cited by Blake and Cecil does not seem wholly convincing for various other reasons: (1) Possibly the inoculation of monkeys with other bacteria associated with influenza than the influenza bacillus would produce practically the same symptoms and lesions as those described, and on this account extensive control experiments are needed before any conclusions of a definite value can be drawn from the results of these experiments with the influenza bacillus; (2) many bacteriologists would take exception to the statement that the influenza bacillus is associated constantly with early uncomplicated cases of influenza, and (3) pathologists would hesitate to accept the statement that the pulmonary lesions in the inoculated monkeys are identical with those of human influenza. At least the question will remain open until the results of much more detailed studies are available, studies not only of material from inoculations with influenza bacilli but also of material from inoculations with other bacteria associated with influenza. In other words, we must not lose sight of the facts that other bacteria found in influenza may give similar experimental results; that the constant presence of the influenza bacillus in influenza has not been demonstrated conclusively, and that it has not been shown that lesions unquestionably peculiar to influenza have been reproduced in monkeys inoculated with influenza bacilli. It may, however, be stated that virulent influenza bacilli may cause an acute infection of the respiratory tract when inoculated in monkeys.

SNAPPING HIP

It is not always grave and dangerous diseases that bring the patient to the physician; frequently symptoms that are trivial, so far as their effect on health is concerned, are responsible for the call, on account of the annoyance they produce. Such a minor ailment is the peculiar condition "snapping hip." The patient complains that flexion and extension of the hip, such as occurs during walking, produces a peculiar snapping sensation on the outer side of the joint which, at times, may be audible to by-standers even at distances of 20 or 30 feet. Mayer¹ has recently described four cases. In his cases the phenomenon was due to a line of thickened fascia lata catching behind the great trochanter. Flexion of the thigh stretches the fascia, which finally, like a taut bow string, is suddenly released and snaps back in front of the trochanter. Propping² calls attention to the fact that Perrin was the first to describe this phenomenon, before a meeting of the Société de Chirurgie de Paris in 1859, and at that time demon-

strated its mechanism. In 1912 Ebner³ collected the reports of twenty-eight cases, to which Propping has added two more. In one of Propping's cases he demonstrated that the cause was a habitual dislocation of the head of the femur. He believes that in many cases the snapping is wholly under the control of the patient, and that it has a hysterical basis. The patient can produce the snapping sensation and sound voluntarily, whenever he desires. Manon⁴ has also described a case recently. He found that simple transverse section put an end to the disturbance. It has been known for some time that there is normally a line of thickening in the fascia lata which runs from the iliac crest downward just in the line of the posterior margin of the great trochanter—the tractus cristofemoralis. If this tract becomes abnormally thickened or if the trochanter becomes abnormally prominent, the "snapping hip" may be produced, although a third factor is also necessary, namely, relaxation of the gluteus maximus. Mayer shows that the phenomenon may sometimes be controlled by appropriate strapping, but that in other instances it is necessary to excise portions of the tractus cristofemoralis so as to avoid a reformation of this band.

BOILED VEGETABLES FOR DIABETICS

Von Noorden called attention to the fact that the boiling of vegetables removed some of the carbohydrates, and Allen applied this fact by using thrice boiled vegetables in the dietary of diabetics. Until recently, the degree of removal of carbohydrates from different vegetables under repeated boilings had not been extensively studied from the quantitative point of view. This gap in our knowledge has now been partly filled by the work of Cammidge,⁵ who has analyzed seventeen of the commonly used vegetables after boiling once, twice and three times. He found that the number of boilings necessary to remove all carbohydrate varied with different vegetables. In the case of celery, rhubarb and spinach, two boilings sufficed to remove all carbohydrate. In the case of white turnips and carrots, three boilings were sufficient; but in the case of all the other vegetables tested there was still carbohydrate varying from 0.1 to 1 per cent. after three boilings. There appeared to be no direct relation between the amount of carbohydrate originally present and the number of boilings required to remove it. The serious drawback to the use of thrice boiled vegetables has proved to be the lack of palatability that results. It is difficult to serve in an appetizing form the resultant mass of vegetable material, and the removal of the carbohydrates is accompanied by almost complete removal of the original flavor. This can be remedied to some extent by mixing clear broths or similar flavoring substances with the vegetable purée. It was some time ago suggested by Ruth Wardall that repeated extraction of the vegetables at a temperature considerably below boiling might accomplish the same result as boiling, without interfering so seriously with

the palatability of the vegetables. Cammidge also tested this method of extraction and found that just as satisfactory results could be obtained and that the vegetables were left in a much more palatable condition.

COMMITTEE ON SCIENTIFIC RESEARCH MAKES GRANTS

The Committee on Scientific Research of the American Medical Association has made these grants for scientific work:

- PROF. G. CARL HUBER, University of Michigan, for study of nerve repair, \$400.
- PROF. H. M. EVANS, University of California, for study of the influence of endocrine glands on ovulation, \$400.
- PROF. E. R. LECOUNT, Rush Medical College, for study of extradural hemorrhage and of the hydrogen-ion content of the blood in experimental streptococcus infections, \$200.
- DR. E. E. ECKER, Western Reserve University, for a study of the significance of antianaphylaxis, \$200.
- DR. HENRIETTA CALHOUN, Iowa State University, for a study of the effect of protein shock on diphtheria intoxication, \$400.

THE NEW ORLEANS SESSION

Going to New Orleans by Boat

As previously announced, Dr. Ira J. Haynes, P. O. Box 24, Richmond, Va., is arranging for a party to go by boat from Baltimore to New Orleans. He desires to correspond with physicians who would like to join such a party. The tentative plans for the trip provide that the boat shall leave Baltimore, Friday, April 23, and arrive in New Orleans, April 27. It is proposed that those who desire to do so may use their staterooms during the stay in New Orleans, and obtain breakfast on board the boat. On the return trip, it is planned that the boat leave New Orleans, Friday night, April 30, and reach Baltimore, Wednesday, May 5. It is estimated that the expense for the trip will be about the same as for railroad fare and sleeper, plus hotel expenses for the time occupied by the trip.

It has also been announced that the *Comas*, one of the Morgan Line of steamships, will leave New York, April 21, and sail from New Orleans on the return trip on the morning of May 1. This boat carries seventy first-class passengers. There is space also for thirty second-class passengers. Requests for particulars should be addressed to Mr. A. J. Poston, General Agent of the Southern Pacific Lines, 165 Broadway, New York City.

An Entertainment Feature

The Local Committee on Arrangements announces a novel feature of the entertainment to be provided for visiting Fellows, their wives and guests. This will be a carnival ball to be staged at the President's reception. There will be presented a number of interesting and attractive tableaux. This entertainment is characteristic of New Orleans, and promises to be of great interest to those who will be fortunate enough to be in attendance.

Hotel Accommodations

The chairman of the Committee on Hotels, Dr. J. J. Wymer, 921 Canal Street, New Orleans, reports that arrangements have been completed to handle promptly all requests for reservation for lodgings which may be received from Fellows of the Association. In addition to the available accommodations in the hotels, the Hotel Committee has arranged to assign to visitors a large number of rooms in well appointed boarding houses as well as in private homes. It is urged that Fellows who desire to make such reservations shall communicate with Dr. Wymer as soon as possible. When two or more are traveling in company and are willing to occupy the same room, this should be stated.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

COLORADO

Nursing Course Postponed.—On account of the prevalence of influenza, the opening of the four months' course of public health nursing, notice of which appeared in *THE JOURNAL* of February 7, has been postponed from March 1 to April 1.

Colorado School of Tuberculosis.—During 1919, the Colorado School of Tuberculosis was organized at Colorado Springs, along the lines similar to the Trudeau School of Tuberculosis. Dr. Gerald B. Webb was elected president; Dr. Philip A. Loomis, managing director, and Dr. George Burton Gilbert, secretary. The next course will begin August 2, and will continue until September 10.

DISTRICT OF COLUMBIA

Legislation to Regulate Practice of Osteopathy.—A bill to "regulate the practice of osteopathy in the District of Columbia" has been introduced in the House by Congressman Johnson of Kentucky. At the present time there are no medical restrictions or limitations on the practice of osteopathy in the national capital and any one can engage in the work. The bill provides for the creation of a board of osteopathic examiners; that all osteopaths must be graduates from legally incorporated schools or colleges, with a four years' course of instruction; that osteopaths shall observe all laws and regulations of the District of Columbia relating to the control of contagious diseases, certifying of births and deaths; a penalty of fine and imprisonment is provided for failure to comply with the provisions of the bill. This same bill passed the House two years ago but failed of passage in the Senate.

GEORGIA

New Officers.—The Association of Railway Surgeons of Georgia was organized at Macon, January 28, and the following officers were elected: president, Dr. Allen R. Rozar, Macon; vice presidents, Drs. George R. Maner, Warrenton, Thomas J. McArthur, Cordele, and Thomas H. Hancock, Atlanta, and secretary-treasurer, Dr. Jarrett W. Palmer, Ailey. The next meeting of the association will be held in Atlanta in August.—Emanuel County Medical Association held its annual meeting at Swainsboro, January 21, and elected Dr. Rufus C. Franklin, Swainsboro, president; Dr. Andrew C. Johnson, Garfield, vice president, and Dr. Thomas E. Blackburn, Wesley, secretary-treasurer.

Personal.—The residence of Dr. William J. Little, Vineville, Macon, was damaged by fire to the extent of \$4,000.—Dr. John M. Sigman, Macon, has resigned as director of the United States Public Health Service Hospital at Atlanta and resumed practice in Macon.—Dr. Horace C. Robles, Albany, has been elected health officer of Dougherty County.—Dr. Henry R. Slack, La Grange, was elected president of the Georgia branch of the Johns Hopkins Alumni Association at its annual meeting in Atlanta, February 21.—Dr. Walter E. Barber, Atlanta, has been reelected vice chairman of the Fulton County Board of Health.—Dr. William H. Myers, Savannah, has been appointed chairman of the Savannah health survey.—Dr. Willard E. Quillian, Atlanta, has been elected vice president of the Atlanta Board of Health.—Dr. James T. Ross, Macon, has been reelected chairman, Dr. J. H. Hurd, Rutland, vice chairman, and Dr. Herring Winship, Macon, secretary of the Bibb County Board of Health.

IDAHO

Barracks Made Into Hospital.—The government barracks at Boise have been converted into a military hospital which will accommodate 200 patients. This hospital will care for disabled service men and will in addition be utilized as a general hospital.

Society Organized.—Physicians of Shoshone County met at Wallace recently and organized the Shoshone County Medical Society, electing Dr. Francis Leo Quigley, Wallace,

temporary chairman; Dr. William C. Lindsay, Kellogg, temporary vice chairman, and Dr. Leonard E. Hanson, Wallace, temporary secretary.

ILLINOIS

Personal.—Dr. George W. Alverson, Sciota, is said to have been found guilty, February 28, of the murder of Lawrence Clugston at Bushnell, in July last, and to have been sentenced to imprisonment for life in the penitentiary.

Illinois State Medical Society Proposes Section for New State Constitution.—The Illinois State Medical Society, through a special committee headed by Dr. Charles E. Humiston, has proposed the following section for the new constitution of the state, now before the constitutional convention in Springfield:

Section. The health of the people is essential to the welfare and perpetuity of the state.

"The General Assembly may enact laws to preserve and safeguard the health of the people and to impose licenses upon those undertaking to treat or cure the sick or infirm or to preserve from sickness and infirmity, persons within the state.

"No power shall exist to impose, hereafter, any term or restrictions or give power to any person or persons to treat or undertake to treat any ailment, infirmity or disease of another for pay, reward or compensation, upon any different terms, limitations, qualifications or prerequisites from those granted or limited to every other person or persons, who may hereafter be licensed to undertake to treat or cure the sick or infirm, or to preserve from sickness and infirmity, persons within the state.

The proposition has been submitted to the committee on miscellaneous topics consisting of O'Brien, chairman, Coolley, Lohman, Michaelson, Meinert, Hill, Pincus, Brandon, Paddock, Johnson, W. A. and Hollenbeck. The bill was presented to the convention by delegate George F. Lohman. Physicians and others who are interested in this section may communicate directly with the members of the committee apprising them of their interest in its adoption.

Chicago

Surgeons Hold Clinical Meeting.—The Chicago Surgical Society held an all-day clinical meeting, March 5. Throughout the day there were clinics at St. Luke's Hospital and the dinner and scientific program were held at the University Club in the afternoon.

The Augustana Hospital Drive.—The seven day drive conducted by 1,000 workers to raise \$700,000 for the erection and equipment of a new building for Augustana Hospital closed, February 26, with \$153,266 in the hands of the campaign committee. The construction of the new building will go forward.

Home Nursing School.—The fourth class in the Free Municipal Training School for Home and Public Nursing will open, March 7, with a class of 650. The third class of 831 women was graduated, February 24, and received the diplomas after completing an eight weeks' course in the training school.—It is said that 862 graduates of this school attended 10,360 cases during the recent prevalence of influenza.

Personal.—Dr. Edwin O. Jordan, chairman of the department of hygiene and bacteriology in the University of Chicago, has been made a member of the International Health Board of the Rockefeller Foundation, but will remain with the university.—Dr. Georgiana M. Dvorak Theobald, the only woman physician to serve with the American Red Cross in Siberia as a surgeon of the Czecho-Slovak army, returned from Siberia, February 28.—Dr. Alice K. Hall has been appointed a medical intern in the Los Angeles County (California) Hospital.

Medical Staff Appointments.—The following appointments to the attending staff of Cook County Hospital in the department of medicine have been announced as the result of a competitive examination given Dec. 4, 1919, by the Cook County Civil Service Commission: Drs. Charles H. Spencer Williamson, Ernest E. Irons, Ellis Kirk Kerr, Joseph L. Miller, Arthur F. Byfield, Joseph A. Capps, Walter W. Hamburger, James G. Carr, Willard W. Dicker, Sidney Strauss, Don C. Sutton, Lee C. Gatewood, Frederick Tice, Ludwig M. Loeb, Karl K. Koessler, and Theodore Ticken.

INDIANA

Tuberculosis Association Meeting.—At the annual meeting of the Indiana Tuberculosis Association held at Indianapolis, February 3 and 4, Dr. Gardner C. Johnson, Evansville, was elected president; Dr. Alfred Henry, Indianapolis, vice presi-

dent; Mrs. Ella B. Kahrer, Anderson, recording secretary, and Mr. James W. Lilly, Indianapolis, treasurer.

Leave of Absence to Dr. Hurty.—The state board of health has granted a leave of absence to Dr. J. N. Hurty, its secretary. He will spend his leave in Florida, and during his absence Dr. William F. King, Indianapolis, will be in charge of the office.

New Hospital for Muncie.—The city council of Muncie, after having refused to make an appropriation of \$25,000, requested by the citizens who were seeking to buy the Home Hospital for \$105,000 and convert it into a city hospital, has agreed to make a cash donation of \$15,000 and to give an additional \$10,000 whenever the board of governors desires to enlarge the institution. Home Hospital will continue as a public institution but with a city official represented on the board of governors.

Personal.—Dr. Herman W. MacDonald, New Castle, has been appointed local surgeon for the Big Four System succeeding Dr. Oliver J. Gronendyke.—Dr. Frederick J. Schulz, for thirteen years surgeon of the General Electric Company at Fort Wayne, has resigned.—Dr. Harry E. Sharrer, Hammond, has resigned as district surgeon of the New York Central Line.—Dr. Edgar C. Loehr, Noblesville, has been appointed health officer of Hamilton County succeeding Dr. Frank Hershey, deceased.—Dr. Harvey W. McKane, Indianapolis, has been appointed a director of the division of tuberculosis, one of the new divisions of the department of health created by the last state legislature.—Dr. Paul E. Bowers, superintendent of the Northern Indiana Hospital for the Insane, near Logansport, has resigned to accept the position of superintendent of a hospital in California.

IOWA

Hospital Notes.—The Samaritan Hospital, formerly the City Hospital, Des Moines, has recently been opened to the public and it can accommodate seventy-five patients.

Health Laboratory Finished.—The new bacteriologic laboratories of the Sioux City Health Department have been completed and are in charge of Mr. W. D. Hayes, city bacteriologist.

Personal.—Dr. John M. Knott, who has practiced medicine in Sioux City for over half a century, announces that he will retire from active practice this month and will move to Southern California.

MARYLAND

Increased Appropriation for Medical School.—The governor of Maryland has recommended to the legislature an appropriation of \$42,500 per year for the next two years for the University of Maryland School of Medicine, which is an increase over the former appropriation of \$25,000. The college has also received \$1,000 from the City of Baltimore for its outdoor obstetric department.

Night Clinics at the Hebrew Hospital.—The board of directors of the Hebrew Hospital have opened a night clinic at the hospital which will be held every Tuesday and Thursday evening. There are a number of free day dispensaries connected with the hospitals in this city, but no night dispensaries for the treatment of general diseases in this city or in this part of the country. The visiting physicians of the hospitals will be in attendance at the clinics.

Personal.—Dr. Elmer V. McCollum, Ph.D., Baltimore, of Johns Hopkins University has been made a corresponding member of the Royal Academy of Medicine of Belgium.—Col. Henry Page, commanding officer at U. S. A. General Hospital No. 2, Fort McHenry, who has been recuperating at Raleigh, N. C., from an attack of influenza, has returned to the post to make preparations for his transfer to Denver, Colo., where he will be in charge of General Hospital No. 21.

—Dr. James H. Jarrett, Towson, nestor of the medical profession at Towson, where he has practiced since 1865, celebrated his eighty-eighth birthday last week at his home.—Dr. Ross McC. Chapman, first assistant physician and chief executive officer of St. Elizabeth's Hospital, Washington, has been appointed medical superintendent of the Sheppard and Enoch Pratt Hospital. Dr. Chapman, who will assume his new duties March 15, will succeed Dr. Edwin N. Brush, Towson, resigned after a service of nearly thirty years. In addition to his duties at St. Elizabeth's, Dr. Chapman holds the position of clinical associate in psychiatry and clinical neurology of the faculty of George Washington University, Washington.

MISSOURI

Personal.—Drs. Andrew W. McAlester, Columbia, and Woodson Moss, Columbia, were elected honorary active members of the Boone County Medical Society on account of their long and distinguished service in the profession, and as an expression of the esteem in which they are held.

Electro-Therapeutic Clinic in Kansas City.—The week of May 24 has been selected for the second graduate course of lectures in electrotherapeutics by Dr. Burton B. Grove, Colorado Springs, Colo. The course will precede the annual meeting of the Western Electro-Therapeutic Society which is to be held at the Little Theater, Kansas City, May 27 to 28.

State Medical Association Meeting.—The annual meeting of Missouri State Medical Association will be held at the state house, at Jefferson City, April 6 to 8. The house of delegates and scientific assembly will hold sessions simultaneously on the first day. A bronze tablet in memory of the nine members of the association who died in service during the World War will be dedicated at this meeting.

St. Louis

Memorial to Dr. Steer.—The council of the St. Louis Medical Society has granted a request made by Dr. William T. Coughlin as chairman of the committee of Washington University Alumni Association to erect a memorial to the late Dr. Justin Steer in the hall of the St. Louis Medical Society building.

Dean Resigns.—Dr. G. Canby Robinson, dean of Washington University Medical School, has resigned to accept a position as dean and professor of medicine in Vanderbilt University, Nashville, Tenn. This is the first appointment to the faculty of Vanderbilt since the donation of \$4,000,000 by the general education board to the university.

NEW YORK

Health Center at Hornell.—The common council of Hornell has set apart rooms in a city owned building to house a tuberculosis clinic, which has been in operation for several years, a child welfare station more recently established and a venereal clinic.

Trudeau School Quota Filled.—The Edward L. Trudeau Foundation for Research and Teaching in Tuberculosis of the Trudeau Sanatorium, Saranac Lake, announces that the Trudeau School of Tuberculosis, which will hold its sixth session, June 16 to July 27, has for six months had a capacity enrollment and will be unable to admit any more students.

Personal.—Dr. LeRoy W. Hubbard has resigned as a member of the health board of Mount Vernon and has been succeeded by Dr. John H. Tallman.—Dr. Malcolm F. Lent, Albany, formerly medical director of the Stony Wold Sanatorium, has been appointed supervisor of the division of tuberculosis of the New York State Department of Health.

Division of Industrial Welfare Advocated.—One of the most important works conducted by the public health council of the state department of health during the year 1919 was an investigation of the industrial welfare needs of the state. As a result of a general survey of industrial conditions throughout the state, the council and the health commissioner have recommended the establishment within the department of health of a division of industrial welfare. The council has during the year provided for a period of isolation for typhoid and paratyphoid fever patients; for the exclusion from schools of children suffering with epidemic influenza; for the regular attendance of a physician at all day nurseries in the state, and for the taking of smears in cases of ophthalmia neonatorum.

New York City

Harvey Society Lecture.—The seventh lecture of the Harvey Society series will be delivered at the New York Academy of Medicine, March 13, at 8:30 p. m., by Dr. Otto Folin, professor of physiologic chemistry in Harvard University, on "Blood Chemistry."

Personal.—Thomas J. Preston, Ph.D., dean of the New York Homeopathic Medical College, has resigned.—Col. Henry D. Thomason, M. C., U. S. Army, retired, has been appointed superintendent of the Flower Hospital.—Dr. Frederic L. Barnum, Brooklyn, a member of the Red Cross commission to Siberia, who was recently captured by the bolsheviks, has been released.

Campaign Against Violators of Harrison Law.—At a conference between representatives of the Internal Revenue Department, February 23, plans for a vigorous campaign

against dealers, smugglers and physicians who violate the Harrison narcotic law were formulated. The narcotic squad has been greatly enlarged and the enforcement of the law placed under the direction of James S. Shevlin.

PENNSYLVANIA

Radium Manufacturer Dies.—Mr. Joseph M. Flannery, Pittsburgh, prominently associated with the Standard Chemical Company which is the pioneer industry in producing radium for use by American physicians from native ore, died recently.

Hospital Library Association Organized.—The St. Joseph Hospital, Pittsburgh, has organized a library association to be open to those who patronize the hospital as well as to the physicians of the city and vicinity. Dr. Richard J. Behan is president and Dr. Jacob Rockman, secretary of the association.

New Influenza Cases in Pennsylvania.—Until February 24, the health department figures showed 1,262 new cases of influenza and 383 of pneumonia, with 438 deaths in three days. The Philadelphia reports were: influenza, 193; pneumonia, 161, while Pittsburgh reported 42 of influenza and 53 of pneumonia.

Case Against Physician Non-Suited.—In the case of John W. Conrad against Dr. George N. Highley, Conshohocken, in which damages of \$20,000 were claimed for alleged malpractice in the neglect of his wife during delivery, Judge Swartz granted a non-suit on the grounds that no negligence on the part of Dr. Highley has been proved.

Personal.—Dr. Hugh Hamilton, Harrisburg, is president, and Dr. Samuel P. Heilman, Lebanon, secretary of the Pennsylvania Federation of Historical Societies.—Dr. Joseph Scattergood, West Chester, has been appointed local surgeon of the Pennsylvania Railroad at West Chester, succeeding Dr. Percy C. Hoskins, deceased.—Dr. Charles T. Horn, Lehigh, is president of the newly organized Lehigh Board of Health.—Dr. Ira J. Hain has been made health officer for Reading.

Philadelphia

Personal.—William G. McAllister, superintendent of the bureau of hospitals in the health department, resigned, February 27, the resignation to take effect April 1. He was appointed provisionally to the new bureau a few weeks ago.

Prison Goods for Hospitals.—According to E. J. Lafferty, secretary of the prison labor board, authority to sell prison made goods to all institutions receiving state aid will be asked of the next legislature. An effort will be made to secure the passage of such a law for at present the sale of prison made goods is restricted to county institutions while the product cannot be sold in Philadelphia County. There are approximately 3,200 state wards in the penal institutions of the state at present. Of this number only 10 per cent. are employed. Under the new law all could be employed and made self supporting by manufacturing supplies used by hospitals such as beds, mattresses, sheets and blankets; and the adoption of such a law would make it possible for the Philadelphia Hospital and similar institutions throughout the state to buy largely from the prison labor board.

SOUTH CAROLINA

New Hospital.—A new Salvation Army home and hospital is to be erected at Greenville to cost \$200,000.

Ambulance Given to Roper Hospital.—Having no further use for a motor ambulance, the Charleston Chapter of the American Red Cross has presented its Silver Thimble Fund ambulance to the Roper Hospital at Charleston.

Personal.—Dr. Allard Memminger has been appointed chairman of the board of health of Charleston. The other members are Drs. John Mercer Green, secretary, and Charles P. Aimar, Henry W. DeSaussure and Archibald J. Buist.—Dr. William T. Brockman has been elected mayor of Greer.

SOUTH DAKOTA

Personal.—Dr. George S. Adams, Yankton, has been appointed superintendent of the State Hospital for the Insane, succeeding Dr. Leonard C. Mead, deceased.

New Officers.—Huron Medical Society at its annual meeting elected Dr. Benjamin Thomas, Huron, president; Dr. John C. Shirley, Huron, vice president, and Dr. Lorenzo N. Grosvenor, Huron, secretary-treasurer.—Dr. Mathew J. Hammond, Watertown, has been elected president of the Watertown District Medical Society.

TENNESSEE

State Association Meeting.—The eighty-seventh annual meeting of the Tennessee State Medical Association will be held at Chattanooga, April 6 to 8, under the presidency of Dr. Andrew F. Richards, Sparta.

Chiropractors Enjoined.—Six chiropractors of Memphis were enjoined, January 28, from practicing, in a decision given by Judge Heikell in a case brought by representatives of the osteopathic and medical profession. An appeal was taken to the supreme court.

Personal.—Dr. John S. Freeman, Springfield, has been reelected for a term of four years as health officer for Robertson County.—Dr. Howard M. Francisco has been appointed assistant superintendent of the Central State Hospital, Nashville, and also chief of the neuropsychiatric clinic of Vanderbilt Medical School. He is holding two clinics a week at the medical college and one clinic a week at the Central State Hospital.—Dr. George A. Hatcher, formerly assistant physician at the Central State Hospital, Nashville, has entered private practice at Fayette.

TEXAS

Trachoma Survey.—Asst. Surg. Joseph L. Goodwin, U. S. P. H. S., who has been assigned to make a survey of trachoma in the state, has begun work in Jefferson County, where he will ascertain the prevalence of this disease among school-children.

Unwarranted Liquor Prescriptions.—The criminal district attorney has notified sixteen physicians of Houston to appear before a board of five state officials to explain why hundreds of prescriptions for liquor have been written by them. One of the physicians cited to appear is said to have a record of 388 prescriptions written in December alone.

Course in Public Health Nursing.—With the opening of the winter term the University of Texas will inaugurate a course in public health nursing, consisting of three months' theoretical work to be given at the university in Austin and two months' field work in Houston. This course is similar in length and content to those given in Columbia, Yale, Northwestern, California, Syracuse, Missouri and other universities.

Influenza Closing Order Upheld.—Declaring that the board of health of San Antonio was clothed with power to maintain quarantine measures deemed necessary to protect the public health, and that the state sanitary code is not exclusive, the petition of the First Church of Christ, Scientist, of San Antonio asking for an injunction to restrain the city from closing the churches, theaters, and other public places on account of influenza, was denied by Judge Taylor, February 13.

New Officers.—The board of directors of the Texas Public Health Association, February 10, elected the following officers: president, Dr. Zachary T. Scott, Austin; vice presidents, Dr. Elva A. Wright, Houston, and James H. Allison, Fort Worth; secretary, J. E. Rawlings, Fort Worth, and treasurer, H. A. Rowe, Austin. Dr. Morris H. Boerner, Austin; Frank C. Gregg, Austin; Charles S. Venable, San Antonio; William C. Farmer, San Antonio, and John Potts, Fort Worth, were elected directors.—At a recent meeting held at Angleton, the Brazoria County Medical Association was reorganized with the following officers: president, Dr. Samuel B. Maxey, Angleton; vice president, Dr. Moses H. Eades, Sweeney, and secretary-treasurer, Dr. George G. Wyche, Angleton.—The Central District Medical Association at its annual meeting, January 15, elected Dr. Howard M. Lanham, Waco, president, and Dr. N. D. Buie, Marlin, secretary. Marlin was selected as the next place of meeting.—Johnson County Medical Society at its annual meeting held in Cleburne, elected: president, Dr. Walter R. Washburn; vice president, Dr. Cariolanus V. Ezell, and secretary-treasurer, Dr. William E. Lucey, all of Cleburne.

VIRGINIA

Graduate Course for Colored Physicians.—During the last week in January a graduate course in early diagnosis of tuberculosis was given at Piedmont Sanatorium, Bergeville, for the benefit of the colored physicians of the state.

New Officers.—Wise County Medical Society in Norton, January 20, elected the following officers: president, Dr. John A. Gilmer, Big Stone Gap; vice presidents, Drs. Charles C. Carr, Inman, David A. Dunkley, Tom's Creek, and Daniel M. Moore, Stonega, and secretary, Dr. Claude B. Bowyer,

Stonega. It was unanimously voted that the physicians of Wise County increase their rates 75 per cent.

Personal.—Dr. Joseph E. Taylor has been appointed coroner of Danville succeeding Dr. Edward Howe Miller, resigned.—Dr. John Garnett Nelson, Richmond, was elected commander of the Richmond Chapter of the American Officers of the World War at its meeting for organization, January 30.—Dr. Stuart McGuire, Richmond, was elected president of the Richmond Chapter of the University of Virginia Alumni at its meeting, February 13.

CANADA

Influenza Epidemic Situation.—Influenza is declining in Toronto and other parts of Ontario, and in Montreal and Quebec the situation is said to be well in hand.

Personals.—Dr. James R. Cox who has been spending the last year in Ottawa is leaving for China about the middle of March. Dr. Cox has been a medical missionary in China for a number of years.—Dr. John G. Fitzgerald, Toronto, has been appointed professor of hygiene at the University of Toronto succeeding Dr. John A. Amyot, Toronto, who has been appointed deputy minister of health of the Federal Department of Health, Ottawa.—Dr. Charles K. Clarke, Toronto, dean of the medical faculty of the University of Toronto, has intimated that he will resign shortly.—Dr. Allan Kinghorn paid a visit to Toronto lately before sailing for England on his way to South Africa where he will resume work with the South African Company. Dr. Kinghorn was formerly at Saranac Lake.—Dr. Thomas Archibald Malloch, Montreal, is among the appointments to the Beit Memorial Fund for Medical Research.

GENERAL

Gifts to Medical Schools.—The general education board announces the following contributions for the advancement of medicine: Washington University, St. Louis, \$150,000; Johns Hopkins University, \$400,000, and Meharry Medical School, Nashville, Tenn., \$150,000. The fund given to Johns Hopkins was for the establishment of a full-time teaching system, with complete facilities for a department of obstetrics.

Influenza Statistics.—The health index of the United States Bureau of Census, for the week ending February 14, shows a slight increase in the incidence of influenza and pneumonia in the forty large cities. There was an excess annual mortality of 1,306 per hundred thousand of population as compared to the corresponding week of the median year in the period 1910-1916. At the height of the epidemic of 1918, the excess annual mortality was 4,695 per hundred thousand.

Throat, Nose and Ear Men Meet.—The annual meeting of the middle section of the American Laryngological, Rhinological and Otological Society was held in Cincinnati, February 21, and the following officers were elected: chairman, Dr. Joseph C. Beck, Chicago; vice chairman, Dr. George M. Coates, Philadelphia; secretary, Dr. William B. Chamberlin, Cleveland, and executive committee, Drs. Francis P. Emerson, Boston, Greenfield Sluder, St. Louis, and Lee Wallace Dean, Iowa City.

Medical College Association Elects Officers.—At the annual meeting of the Association of American Medical Colleges held in Chicago, March 2 and 3, Dr. William Pepper, Philadelphia, was elected president; Dr. Thomas Hough, Charlottesville, Va., vice president, and Dr. Fred C. Zapffe, Chicago, was reelected secretary-treasurer. The new executive council consists of Drs. Irving S. Cutter, Omaha; Isadore Dyer, New Orleans; James Ewing, New York City; Charles R. Bardeen, Madison, Wis., and George Blumer, New Haven, Conn.

New Tri-State Officers.—The twenty-second annual meeting of the Tri-State Medical Society of the Carolinas and Virginia was held in Charlotte, February 18 and 19, under the presidency of Dr. Robert C. Bryan, Richmond, Va., and the following officers were elected: president, Dr. John P. Munroe, Charlotte; vice presidents, Dr. John A. Williams, Greensboro, N. C., William W. Fennell, Rock Hill, S. C., and Halstead N. Hedges, Charlottesville, Va., and secretary, Dr. James K. Hall, Richmond, succeeding Dr. Rolfe E. Hughes, Laurens, S. C., who had occupied the position for twelve years and declined reelection. Spartanburg, S. C., was selected as the meeting place for 1921.

Plans of Red Cross.—Dr. Livingston Farrand, chairman of the central committee of the American Red Cross, announces the following plans for the completion of war time obli-

tions and carrying forward the peace time activities. A fund of \$30,000,000 is appropriated for various uses at home and abroad. For obligations to soldiers, sailors and their families, relief demands incident to disaster, and the establishment of a peace program in America, \$13,750,000 is allotted; for general European relief, especially in Eastern Europe, an appropriation of \$15,000,000 is made, and it is estimated that the work of the American Red Cross in Siberia will call for an appropriation of \$1,250,000.

American Congress on Internal Medicine.—The fourth annual meeting of the American Congress on Internal Medicine was held in Chicago, February 23 to 28, under the presidency of Dr. Glentworth R. Butler, Brooklyn. The scientific program included clinics, lectures and laboratory demonstrations in the mornings; clinical talks and demonstrations in the afternoons, and on Wednesday evening a joint meeting of the congress and the Chicago Medical Society at which Dr. Alfred S. Warthin of the University of Michigan, Ann Arbor, delivered an illustrated address on the "Medical Aspects of Gassing in Warfare, with Particular Reference to Mustard Gas." On Thursday the members of the congress inspected the Chicago Municipal Tuberculosis Sanatorium. Baltimore was selected as the next place of meeting.

Physician as British Ambassador.—The medical profession will be interested in the appointment of Sir Auckland Geddes as British ambassador to the United States which marks another chapter in the public career of a physician. Our London correspondent commented on the singular fact that two qualified physicians held the rank of cabinet minister in the British government—Sir Auckland Geddes and Rt. Hon. Christopher Addison, first minister of health. Sir Auckland Geddes, who was born in Scotland in 1879, was a pupil of Sir William Turner at Edinburgh, where he graduated M.D. in 1903, and later served as demonstrator and assistant professor of anatomy. From Edinburgh he was called to the chair of anatomy at the Royal College of Surgeons of Ireland, and during this period he made many contributions to the literature of anatomy and embryology, with here and there a note on the mechanical and structural factors of pathologic process. In 1913, Dr. Geddes was appointed professor of anatomy at McGill University. At the outbreak of the European war, he obtained leave from McGill University to enter military service. In 1916 he was appointed director of recruiting and when in August, 1917, recruiting was placed under civilian control, Sir Auckland became minister of national service. His election to parliament from Hampshire and his appointment to the ministry of reconstruction followed. In addition he assumed for a time the duties of president of the Local Government Board, in which position he was instrumental in the passage of the act creating the ministry of health. In April, 1919, he was appointed principal of McGill University and it was expected that he would assume the duties of the position in the fall, but this was prevented by his subsequent appointment as president of the board of trade and now as ambassador to the United States. His active interest in medical education is evidenced by his critical remarks on the record of the medical profession of England during the war, as reported in *THE JOURNAL*, Jan. 3, 1920, p. 43.

Annual Congress on Medical Education and Licensure.—The Annual Congress on Medical Education and Licensure under the auspices of the Council on Medical Education of the American Medical Association, the Association of American Medical Colleges and the Federation of State Medical Boards of the United States, was held this week at the Congress Hotel, Chicago. The sessions lasted three days. There were about 250 delegates present. This has been the most satisfactory conference held on medical education for several years. Instead of three disjointed programs as heretofore held by the three organizations above named, this year a joint session was arranged, by which duplications were avoided, the program as a whole was better arranged and more ample time given for discussion. It appears also

that the speakers were invariably men of ability and competent to speak with authority on the subjects with which they dealt.

Besides the usual reports of progress by the officers of the Council on Medical Education and the presidents of the other organizations, papers were presented; there was a symposium on "The Needs and Future of Medical Education," by Dr. George E. Vincent, president of the Rockefeller Foundation, New York City; Dr. Ray Lyman Wilbur, president of Leland Stanford University, California; Dr. Charles F. Thwing, president of the Western Reserve University, Cleveland; Mr. Abraham Flexner, secretary of the General Education Board, New York City. This was followed by a paper on "The Larger Function of State University Medical Schools," by Dr. Walter A. Jessup, president of the State University of Iowa, Iowa City. Two papers on "Research in Medical Schools" was given by Dr. Oskar Klotz, professor of pathology, University of Pittsburgh School of Medicine, Pittsburgh, and Dr. G. Canby Robinson, dean, Washington University School of Medicine, St. Louis. A great deal of discussion was given to the subject of "Full-Time Clinical Professors" following the remarks by the chairman of the Council on Medical Education and the paper by Dr. William Darrach, dean of Columbia University College of Physicians and Surgeons, New York City.

The subject of medical licensure was presented in the address on "Coordination of Effort in Medical Licensure,"

by Dr. David A. Strickler, president of the Federation of State Medical Boards, Denver, and in a paper on "Interstate Relations in Medical Licensure," by Mr. Francis W. Shepardson, director of the Department of Registration and Education of the State of Illinois. "Graduate Medical Education in the United States and Europe" was presented in articles by Dr. Louis B. Wilson, director of the Mayo Foundation for Medical Research, Rochester, Minn., and Dr. Walter L. Bierring, secretary of the Federation of State Medical Boards, Des Moines, Iowa.

Following were a series of reports on the teaching of the various pre-medical sciences by members of the Committee on Medical Pedagogy of the Association of American Medical Colleges. Among those presenting reports were: "Anatomy," Dr. Charles R. Bardeen, dean, University of Wisconsin Medical School, Madison; "Histology and Embryology," Dr. F. C. Waite, professor of histology and embryology, Western Reserve University School of Medicine, Cleveland; "Neuro-Anatomy," Mr. Irving Hardesty, professor of anatomy, Tulane University School of Medicine, New Orleans; "Physiology," Dr. E. P. Lyon, dean, University of Minnesota Medical School, Minneapolis; "Biological Chemistry," Dr. Otto Folin, professor of biological chemistry, Medical School of Harvard University, Boston; "Pharmacology," Dr. C. W. Edmunds, assistant dean, University of Michigan Medical School, Ann Arbor; "Pathology," Dr. James Ewing, professor of pathology, Cornell University Medical School, New York City; "Bacteriology and Parasitology," Dr. A. I. Kendall, dean, Northwestern University Medical School, Chicago, and "Public Health and Preventive Medicine," Dr. Victor C. Vaughan, dean, University of Michigan Medical School, Ann Arbor.

It had been frequently stated that a difficulty in previous conferences was the failure to provide ample time for discussion. The present conference, therefore, was all the more successful owing to the fact that there appeared to be no difficulty in this respect.

A more complete report, including abstracts of the various papers and discussions, will appear beginning in the next issue of *THE JOURNAL*.

FOREIGN

Cancer in Workers on Coal Briquettes.—The authorities in Germany are now collecting data in regard to cancer in persons engaged in making coal briquettes. In the last five years there have been ten cases of epithelioma recorded in a total of 2,500 workers. It was on the face or arm in five

SIR AUCKLAND GEDDES, M.D.

cases and the scrotum in five others. Conjunctivitis is also common among these workers.

Appointments.—The president of the Royal College of Physicians, London, has appointed Francis W. Andrew, Harveian orator, and Dr. Reginald C. B. Wall, London, Bradshaw lecturer for 1920.—The council has appointed Dr. Martin W. Flack, London, Milroy lecturer for 1921, and has awarded the Oliver-Sharpey prize for 1920 to Prof. Emil Roux of the Pasteur Institute, Paris.

Memorial to Revilliod.—A bronze medallion with the bust of the late Professor Revilliod in bas relief is to be installed in the amphitheater of the medical department of the University of Geneva, Switzerland, the scene of his labors. The memorial is to be presented by his former pupils and friends, and subscriptions of 30 francs or more entitle the donor to a replica in bronze of the medallion. Address Dr. Maillart, 6 rue de la Synagogue, Geneva.

Diffraction Phenomena in Blood Cells.—The *Nederlandsch Tijdschrift* relates that Dr. A. Pijper of Bethal, Transvaal, in the midst of the difficulties of practicing medicine in Africa, has undertaken research which has demonstrated certain diffraction phenomena in blood cells and in cocci, which may serve for micrometric purposes. The South African Institute for Medical Research has awarded him 100 guineas as a token of appreciation.

Deaths in the Profession Abroad.—Dr. M. Candela Plá, a pioneer in the introduction of operative gynecology and radium treatment into Spain, professor of obstetrics and gynecology at the University of Valencia, aged 73.—Dr. C. Bozzolo, senator and professor emeritus of clinical medicine at the University of Turin, one of the first to study the spread of cancer by the lymphatics, and author of numerous works on pneumonia, meningitis and ankylostomiasis, aged 75.—Dr. L. Barajas, one of the best known specialists in ear and throat work at Madrid.

Data on Anesthetics.—Prof. W. Denk of Vienna appeals to the members of the profession for data on untoward by-effects or after-effects of all kinds from local anesthesia and nerve blocking, including intraspinal anesthesia. He is compiling records for an address on the subject to be delivered at Vienna in June, 1920, and he states that he would be very grateful for any information to aid him in the task. He inquires particularly for the reasons if any have abandoned the use of any of these methods for anesthesia. He is first assistant at the Klinik Eiselsberg, Alserstrasse 4, Vienna, Austria.

Reappearance of the Liège Médical.—After five years' suspension, the *Liège Médical* makes its appearance anew as the organ and mouthpiece of the profession in the Liège district, as in the seven years before the war. The editorial staff is all local, and includes many well known names, Nolf, Stassen, Malvoz, Fraipont, Beco, Henrijean, Delrez, Fredericq, Weekers and Stockvis, all members of the medical faculty of the university. The first issue tells of the presentation of a souvenir album to Dr. Herman, president of the *Fédération Médicale Belge*, in token of appreciation of his "superhuman efforts in medical care for 600,000 families during the war."

LATIN AMERICA

Epidemic Poliomyelitis in Argentina.—The *Brazil-Médico* states that Dr. Kraus, director of the public health service of Argentina, has gone to Santa Fé to investigate some cases said to be infant paralysis.

Deaths in the Profession.—At Rio de Janeiro, Dr. H. Cesidio Samico, aged 74, and Dr. J. Saturnino de Brito of the public health service.—Dr. E. G. Figueroa, a well known stomach specialist of Buenos Aires.—Dr. F. de la Vega, for many years connected with Hospital Rivadavia at Buenos Aires, was killed, December 30, by a bandit.

Quarantining Against Influenza at Rio.—Several ships arriving at Rio de Janeiro from Europe with influenza on board and several deaths from alleged influenza during the passage, have been quarantined and the passengers held, by order of the director-general of the public health service, Dr. C. Chagas, pursuing the policy inaugurated by his predecessor and demanded by the public press.

Influenza in Mexico.—Influenza continues to spread in Mexico. In Mexico City there were 106 deaths, February 24; 100, February 25, and 86, February 26. All churches, moving picture houses and schools have been closed. It is stated that there are 3,000 persons sick with the disease at Tampico, the disease having taken a virulent form of late.

Numerous cases are also reported from the state of Sonora and the city of Puebla.

Personal.—Dr. Louis Shapiro of the Rockefeller Institute is now in Colombia at the request of the Colombian government, making a study of the prevalence of leprosy, malaria and hookworm disease, in order to submit a plan for its eradication.—Dr. Victor G. Heiser of the Rockefeller Foundation has just returned to New York after a trip to Porto Rico with Dr. Grant to make a study of sanitary conditions of the island, especially as regards hookworm disease. Since the appearance of the hookworm infection in Porto Rico, the government of the island has spent several hundreds of thousands of dollars to combat the disease.

Health Conditions in the Army

For the week ending February 20, there was continued improvement in the health of the troops, although influenza and pneumonia cases still appear. The number of new cases reported showed a marked decline. There was an increase in the number of new cases of measles. The admission and noneffective rates also declined, the death rate being slightly more than half the rate for the preceding week. Among the American forces in Germany, influenza and pneumonia remained practically the same, while measles showed a decline. Among the American forces in Siberia, twelve new cases of pneumonia were reported as against two for the previous week.

Army Reorganization Bill

The Army Reorganization Bill has been reported from the House Committee on Military Affairs by Congressman Kahn of California, chairman. Under its provisions, there will be 1,820 officers of the medical department. Medical officers who served in the Army during the World War and are now in the Medical Reserve Corps will be eligible for appointment in the regular Army on July 1, 1920, under the terms of this bill. Approximately 700 such vacancies will have to be filled, and the selections will be made from medical men who served in the war and who are now in private life, or from medical officers who are now holding temporary commissions effective until May 1, 1920, only.

The bill provides that a colonel in the Medical Corps shall be not less than 48 years of age; lieutenant-colonel, 45; major, 36; and that no person shall be appointed to a grade higher than that held by him on Nov. 11, 1918—the date of the armistice.

The selection of these medical officers will be made by a board consisting of the general of the Army, three bureau chiefs and three general officers of the line.

It is intended to use the material developed and trained during the war in filling vacancies and the high age limit of 54 years is set in order to obtain the services of men of advanced years and high abilities for some of the technical staff positions.

The bill provides for commissioned rank to members of the Army Nurse Corps. As a result of a caucus of House members, the bill contains no provision whatever regarding a policy for universal military training. There apparently is no prospect whatever that this policy will be established by the present Congress. Its future enactment into law will depend on some program to establish it in schools and colleges and in that way educate the people to its merits. The bill as reported by Congressman Kahn will be the basis of all Army legislation which must be enacted by July 1, because the present law applying to Army personnel is effective only to that date.

Foreign Correspondence

MEXICO CITY

Feb. 22, 1920.

Dr. Noguchi in Mexico

Next to the death of Dr. D. Eduardo Licéaga, already mentioned in THE JOURNAL, the event that has attracted most attention among the medical profession in this city has been the visit of Dr. Hideyo Noguchi. He arrived from Yucatán, February 3, and remained here until the 8th, when he returned to New York. Accompanied by Israel J. Kligler, Ph.D., a member of the Rockefeller Institute for Medical Research, he attended the first session of the National Academy of Medicine, of which he is an honorary member. Two days afterward, by special invitation of the board of trustees of the Mexican Medical Association, he gave a brilliant lecture relative to his scientific work on the etiology of yellow fever, carried out in Ecuador and more recently in the city of Mérida. The lecture was illustrated with slides and was given in Spanish, in which the New York bacteriologist can make himself understood. He said that his mission in this country was not a personal undertaking, but that he had been sent by the Rockefeller Institute to try to confirm in Mexico the discovery he had made in South America of *Leptospira icteroides*. He added that, using the well-known technique, he had been able to demonstrate the presence of this germ in four cases of fever he had observed at Mérida, and that he had delivered several specimens of the micro-organism to the superior board of health. He showed several live cultures of *Leptospira* in the dark field and in various stains, as well as the vaccine prepared from these germs, which, it is hoped, may serve to immunize against yellow fever, as similar products have done in other diseases. He also showed the specific serum which possesses curative properties, and the preserved bodies of guinea-pigs that had died of experimental yellow fever, in which could be seen lesions very similar to those produced by the disease in man. He ended by saying that in his work he had been assisted by Kligler and several Mérida physicians. Noguchi was very much applauded by his audience, which included several hundred physicians and many medical students. It can be said that while this lecture did not add to our knowledge of the bacteriology of yellow fever, it strengthened the belief in the causal rôle of *Leptospira*, through its having been isolated in the cases studied recently. Noguchi also demonstrated before several Mexican physicians in one of the departments of the board of health his modification of the Wassermann reaction. While in the city, Noguchi was lavishly entertained both by officials and by private citizens. The impression left by the visit of the Rockefeller representatives could not have been better, and we hope that more American scientists of the same category may come to this country to help us in our struggle for the improvement of health conditions and to cement the bonds that unite the members of the medical profession in the two countries.

The Influenza Situation

Against our hopes based on the long intervals that usually separate the epidemics of influenza, this disease has reappeared. As in previous instances, the epidemic has extended from north to south, after having presented itself in the United States. Owing perhaps to the fact that we are having very mild weather, or for some other reason, the number of those attacked is smaller than in the United States. The disease so far has been mild, the simple catarrhal form exceeding the hemorrhagic cases. The cases of influenzal pneumonia, pleuritis, and bronchopneumonia are also less numerous and there have been no nervous sequelae. There are no official statistics on which to base my opinion, but the general impression is that the mortality has not increased as in 1918; that the persons who contracted the disease in the preceding epidemic have not been attacked this time, and the largest morbidity has been among children.

Personal

Dr. G. Mendizábal, president of the Mexican Medical Association, has been made by the king of Spain commander of the Real Orden de Isabel la Católica.—Dr. José León Martínez, former professor of clinical medicine in the School of Medicine, has been appointed director of the Military Hospital of this city, and of the Military Medical School attached to it, receiving the rank of colonel.—Dr. Germán

Díaz Lombardo, vice president of the Academy of Medicine, has returned from his trip to the United States, where, for the purpose of study, he visited the cities of Chicago and New York.—Dr. Agustín Chacón, an ophthalmologist, member of the academy and former professor of the School of Medicine, has died as a result of a gastrorrhagia.

PARIS

Jan. 29 1920.

The Creation of the Office of Minister of Hygiene

Prime Minister Clemenceau having resigned, M. Millerand, his successor, was charged with the organization of a new cabinet. He has introduced an innovation by creating a new ministerial office, that of ministère de l'hygiène, de l'assurance et de la prévoyance sociales (social hygiene, social insurance and social provision). The question of appointing a special minister of public health has been considered for some time. The question first came up in 1902, at the time the law in regard to the protection of public health was passed. It was again agitated when the application of the law was extended so as to include the antituberculosis and social hygiene dispensaries. In 1913, Dr. Vaillant, a Paris deputy, had taken the initiative and demanded the creation of the office of minister of public health, and M. Mirman, at that time directeur de l'assistance et de l'hygiène publiques au ministère de l'intérieur, had favored such action. In 1916, Jules-Louis Breton, deputy of the department of Var, presented a more modest proposal to the chamber of deputies. He requested that the office of undersecretary of state for hygiene, in connection with the service of the minister of the interior, be established. The year before, on the initiative of M. Millerand, at that time minister of war, the government had created the office of undersecretary of state for the Service de santé militaire. But during the great epidemic of influenza that raged in France in 1918, it was found that the duties and functions of two duly appointed officials clashed, namely, the undersecretary of state for hygiene, associated with the office of minister of the interior, and the undersecretary of state associated with the Service de santé militaire. In view of this fact, M. Clemenceau organized, under his chairmanship, a ministerial conference, grouping together all the services having to do with health and hygiene, which at that time were scattered through five ministerial departments. Under Prime Minister Millerand this temporary arrangement has taken on a permanent form, and the office of minister of hygiene has been conferred on J.-L. Breton, as already stated. Having been chemical engineer, adviser to the chamber of deputies in matters of social hygiene, and author of the bill aiming to suppress the use of white lead in building paint, Breton was the logical choice for the new post.

A Physician's Responsibility in Accidents Following Subcutaneous Injections

A physician residing in one of the departments outside of Paris is facing, as the result of the death of a client, in whom an abscess developed after an injection, a charge of homicide through imprudence. The Société de Médecine de Paris has interested itself in the case, and has drawn up and approved the subjoined conclusions, which will be presented to the court by the counsel for the defendant:

The Société de Médecine de Paris hereby gives expression to the following opinions: 1. The use of subcutaneous injections of camphorated oil and of strychnin is absolutely indicated in cases of severe typhoid, in order to keep up the general condition of the patient and to forestall cardiac insufficiency. 2. The dose of strychnin employed (6 mg.) is less than the amount that may be injected with safety during a twenty-four hour period. 3. Abscesses may occur during the course of typhoid without giving rise to the presumption of error in the matter of asepsis. 4. The physician in charge of the case is always the judge of the treatment to be employed, and he can modify it according to the exigencies that arise.

Medical Service in the Liberated Regions of France

The minister of liberated regions offers the following conditions to physicians who desire to take up their residence, at least temporarily, in such localities of the liberated regions as are deprived of civilian physicians: 1. The physicians accepted for such service will be placed by the minister of war at the disposal of the minister of liberated regions, but with the stipulation that, whenever local conditions will permit, a certain limited amount of military service may be required. 2. They will continue to be governed by military statutes. 3. Those who are receiving a salary of less than 1,000 francs a month will receive from the minister of liberated regions such additional sum as will make up such total

amount. 4. They will be engaged for a period of three months, which will be renewable, and will be authorized to accept a paying clientele. 5. The minister of liberated regions will provide them with an automobile, and will furnish them gratuitously with tires and gasoline in such amounts as may be necessary to cover their allotted territory.

The first vacancies to be provided for are permanent posts in infirmaries and hospitals, which must be installed and organized in connection with the establishment of certain important centers where laborers needed in building up the desolated regions will be brought together.

A Commemorative Ceremony

A ceremony commemorative of the members of the medical corps who died at the post of duty was held at the Sorbonne, January 25, under the auspices of the Association générale des médecins de France and the Association générale des pharmaciens. The various medical faculties and schools of pharmacy, the academy of medicine, the learned and professional societies and the Service de santé militaire felt called on to take part in this solemn occasion. M. J.-L. Breton, minister of hygiene, presided at the ceremony. He was assisted by Dr. Mourier, former undersecretary of state for the Service de santé militaire, and by Dr. Roger, dean of the Faculté de Médecine de Paris.

In his opening address, Dr. Bellemontre, president of the Association générale des médecins de France, mentioned the fact that out of 22,000 French physicians and surgeons 18,000 were mobilized, and that the percentage of losses in the Service de santé militaire was next to that of the officers of the infantry.

LONDON

Feb. 7, 1920.

Medical and Surgical Units at the London Hospitals

The system of forming medical and surgical units for teaching and investigation at the London hospitals, described in previous letters, is extending. At St. Thomas's, Dr. E. H. Starling, F.R.S., professor of physiology at University College, has been appointed director of the medical unit, and assistant directors in pathology and clinical medicine are about to be appointed. Sir C. Wallace, surgeon to the hospital, has been appointed director of the surgical unit. At University College, Dr. T. R. Elliott, F.R.S., physician to the hospital, has been appointed director of the medical unit, and Dr. J. W. McNee, recently assistant to the regius professor of medicine and to the professor of pathology at Glasgow, has been appointed deputy and first assistant. Dr. F. M. R. Walshe has been appointed second assistant to the director to control neurologic teaching and research, and also to take charge of electrotherapeutics and massage. The director of the surgical unit is Mr. C. C. Choyce, with two assistants. The directors of units are responsible for the general arrangements of systematic teaching on the principles of medicine and surgery. The instruction of junior students in physical signs and elementary laboratory methods, and the systematic demonstrations and lectures for senior students are to be organized by them, although the teaching of these courses is in certain cases given by other members of the staff. Every student is to take duty during his first year for two months' clerking and two months' dressing with the medical and surgical units, respectively. These terms of clerking and of dressing are intended to follow as far as possible a four months term of duty with other members of the staff. Thus, every student will in due course pass through one or the other unit. During his course of two months' duty under the director of the medical unit, the student will be attached for clinical clerking to some of the special departments, such as the cardiographic, under Dr. T. Lewis. The directors of the units and their assistants have ample accommodation and facilities for research work in the Graham laboratories of pathology.

The Vaccination Position

In his report to the late Local Government Board (now merged in the Ministry of Health), the principal medical officer, Sir George Newman, refers to a number of isolated outbreaks of smallpox, comprising 206 cases in all and affecting fifty-eight sanitary areas. Thanks to the anti-vaccination agitation and the recognition by law of the "conscientious objector," the percentage of children successfully vaccinated in 1917 was only 43.3, and the percentage exempted from vaccination was as high as 37.9. Compared with twenty years ago, these figures are significant, for in

1898, 61 per cent. of the children were successfully vaccinated and only 5 per cent. were exempted. In the years following the last serious epidemic of smallpox (1901-1904), the percentage of vaccinated children rose above 70. On the other hand, the war has led to a great increase of the revaccinated. Although revaccination was not made compulsory on all men who joined the army, a large proportion were revaccinated. At present a greater number of the male population between 20 and 40 years of age have been revaccinated than in former years. Revaccination has also extended to women, for a large proportion of women who joined the auxiliary services of the war were revaccinated. The position, therefore, is that while the adult population is better protected than before, children are less well protected. In the recent cases of smallpox, prompt notification, speedy isolation and diligent inquiry as to contacts, to secure their immediate vaccination, were successful in preventing the spread of infection. But it is held that such measures cannot be relied on when smallpox breaks out in a population unprotected by vaccination. In prevaccination days, the deaths from smallpox were most numerous at ages under 10, and the majority occurred at ages under 5. The unprotected state of the child population of this country is therefore a great danger.

Tests of Cure in Venereal Diseases

The Ministry of Health has issued a memorandum suggesting tests which should be applied before patients suffering from gonorrhea and syphilis can be considered cured. In the case of gonorrhea, a careful search should be made with the urethroscope for signs of urethral disease. While under examination the patient resumes his ordinary mode of life, sexual abstinence alone being enjoined. On three occasions at intervals of a week he comes for the test. Films are prepared from any moisture obtainable from the urethra, secretions expressed from the prostate and seminal vesicles and centrifugalized urine. On at least one occasion the examination of the films is supplemented by the taking of cultures, and when possible a complement fixation test is performed on the serum. In order to provoke a urethral discharge, the patient is encouraged to resume his usual habits as regards alcohol, pickles, curries, etc. For the same purpose full-sized bougies are passed, and instillations of silver nitrate are made, or a provocative injection of gonorrheal vaccine is given. If all these tests prove negative he is provisionally discharged as cured, but is warned to return should he notice anything suspicious. In the case of women the difficulty of being certain of cure is greater. The tests are best made immediately before or after the periods. Provocative treatment is carried out by the application of 15 per cent. silver nitrate solution to the cervical canal or by vaccine injections. Films and cultures are prepared from the cervical canal and urethra. Culture methods are essential in the female owing to the difficulty of finding the gonococcus in films. Whenever possible, the complement fixation test should likewise be employed.

In syphilis, the time factor is of great importance. When more than four years have elapsed since the original infection, the risk of contagion is minimal. Until this period has elapsed, the patient should report for examination at intervals of one month during the first year and of three months during the second. The examination includes inspection of all surfaces of the skin and mucous membranes, and the Wassermann test. At the end of the first and second years of the treatment, a small provocative dose of an arsphenamin compound is given, and the Wassermann test is performed a week later. If four years have passed since infection, the patient is regarded for all practical purposes as noninfectious. He is advised, however, in his own interest to continue under observation until it becomes probable that the disease has been eradicated.

Marriages

EMORY GRAHAM ALEXANDER to Miss Harriet C. Deaver, both of Philadelphia, February 17.

ABRAHAM JABLONS to Miss Ruth Leona Taylor, both of New York City, January 20.

ALBERT G. MILLER to Miss Katherine E. Frutchey, both of Philadelphia, February 10.

Deaths

Edward Chauncey Register, Charlotte, N. C.; University of the City of New York, 1895; aged 59; editor of the *Charlotte Medical Journal* since 1891; president of the Medical Society of the State of North Carolina in 1906, and the Charlotte Medical Society, and president of the State Board of Medical Examiners from 1898 to 1902; of the American Medical Editors' Association in 1915, Medical Councilors of North Carolina from 1903 to 1906, and of the Tri-State Medical Association of the Carolinas and Virginia in 1915; physician in charge of St. Peter's Hospital, Charlotte; formerly professor of practice of medicine in the North Carolina Medical College, Charlotte; president and chief physician of the Charlotte Sanatorium from 1906 to 1916; one of the most prominent and beloved physicians of North Carolina; died in the Charlotte Sanatorium, February 18, from pneumonia.

John Van der Poel * New York City; College of Physicians and Surgeons in the City of New York, 1881; aged 62; a member of the American Association of Genito-Urinary Surgeons and its president in 1910; a member of the American Urological Association, and a fellow of the New York Academy of Medicine; a member of the staff of New York and Mount Sinai hospitals, and attending genito-urinary surgeon to Washington Heights Hospital; lecturer on obstetrics and later lecturer in clinical genito-urinary diseases in the University of the City of New York; a member of the staff of a hospital at Chateau Annel, France, during the World War; died, February 22.

James Freer Richardson, Winnipeg, Man.; University of London, 1911; M.R.C.S. (Eng.), 1911; L.R.C.P. (Lond.), 1911; aged 35; a medical missionary of the Church Missionary Society at Peshawur, and Dera Ismail Khan, India, who on the outbreak of the World War enlisted and was sent to Mesopotamia as captain of the Thirtieth Advance Casualty Clearing Station, then transferred to Mosul, and later to the Forty-Ninth Indian General Hospital on the Afghan frontier; died in Afghanistan, Nov. 27, 1919, from pneumonia.

Frank James Schoenenberger * New York City; Bellevue Hospital Medical College, 1896; aged 44; adjunct professor of urology in Fordham University, New York City; a member of the New York Academy of Medicine; assistant genito-urinary surgeon to the City and Sydenham hospitals; genito-urinary surgeon to the Correctional Hospital and surgeon to the state penitentiary; died in Roosevelt Hospital, New York City, February 20, after an operation for the removal of gallstones.

Henry Ardagh Kingsmill, London, Ont.; Western University, London, Ont., 1895; aged 52; demonstrator of anatomy in his alma mater; surgeon of the Seventh Regiment Fusiliers, and after the outbreak of the World War president of the standing medical board of western Ontario; then captain, C. A. M. C., with service in England, and later adjutant and registrar of the Military Hospital, London; died, February 11, from pneumonia following influenza.

Philip Thomas Kennedy * Hartford, Conn.; Harvard University Medical School, 1909; aged 36; a specialist in pediatrics; for two seasons in charge of the Boston Floating Hospital; pediatricist to St. Francis' and the Baby hospitals and St. Agnes' Home, Hartford; died in St. Francis' Hospital, February 14, after an operation for abscess of the lungs.

Wilford Hall Crutcher, Bartlesville, Okla.; Barnes Medical College, St. Louis, 1908; aged 37; formerly assistant superintendent of the Nebraska State Hospital for the Insane, Ingleside; who served during the World War as lieutenant, M. R. C., U. S. Army, and was discharged, Jan. 27, 1919; died, February 12, from pneumonia.

Arthur Brownell Wright * Hartford, Conn.; College of Physicians and Surgeons in the City of New York, 1895; aged 51; for eight years a member of the staff of the Manhattan Institute for the Insane; and since 1903 chief medical examiner for the Traveler's Insurance Company; died, about February 4.

José Maria Ferrer * New York City; College of Physicians and Surgeons in the City of New York, 1879; aged 62; a native of Cuba; a member of the New York Academy of Medicine; visiting physician to St. Vincent's and French hospitals, New York City; died, February 23, from heart disease.

Joseph Patrick Murphy, Brookline, Mass.; Harvard University Medical School, 1884; aged 58; also an attorney; assistant chief of the division of child hygiene of the Boston Board of Health since 1911; died in the Peter Bent Brigham Hospital, Boston, February 18, from bronchopneumonia.

Dwight Culver Smith, Goff, Kan.; University Medical College of Kansas City, Mo., 1904; aged 41; a member of the Kansas Medical Society; captain, M. C., U. S. Army, during the World War, with service overseas, and discharged, March 7, 1919; died, February 15, from influenza.

Thomas Alexander Lee, Jr., Hibbing, Minn.; George Washington University, Washington, D. C., 1908; aged 36; who served during the World War as lieutenant, M. R. C., U. S. Army, and was discharged, Aug. 15, 1919; died at the home of his father in Washington, February 19.

Albert Mealey Dunlap, Cleveland; Cleveland College of Physicians and Surgeons, 1905; aged 37; lieutenant, M. C., U. S. Army, during the World War, and discharged, Jan. 16, 1919; was taken ill with pneumonia at the home of a patient, and died there, February 10.

George William Brock * Atlanta, Ill.; Northwestern University Medical School, Chicago, 1910; aged 41; who served as captain, M. R. C., U. S. Army, during the World War, and was discharged, March 18, 1919; died, February 17, from an infection following influenza.

John Beriah Ellis, Springfield, Mass.; Bellevue Hospital Medical College, 1871; aged 74; for many years a practitioner of Little Falls, N. Y., and health officer and coroner of Herkimer County; died at the home of his daughter in Springfield, February 10.

Ernest Henry Noyes * Newburyport, Mass.; Harvard University Medical School, 1880; aged 66; city physician of Newburyport; a member of the staff of the Anna Jaques Hospital; died, February 7, from valvular heart disease.

Samuel Dixon Sturgeon, New Galilee, Pa.; Western Reserve University, Cleveland, 1884; aged 69; a member of the Medical Society of the State of Pennsylvania; died at the home of his sister in New Brighton, Pa., February 12.

Willet Jeremiah Herrington * Bad Axe, Mich.; University of Michigan, Ann Arbor, 1882; aged 63; for fourteen years surgeon in chief of the Hubbard Memorial Hospital; died in that institution, February 10, from pneumonia.

John H. Baldwin, Calera, Okla.; Memphis (Tenn.) Hospital Medical College, 1895; aged 60; for two terms a member of the state legislature from Bryan County; died, February 14, from pneumonia following influenza.

Lovick W. Phillips, Girard, Ala.; Tulane University, New Orleans, 1861; aged 84; surgeon of the Thirty-Second, Georgia, Infantry, C. S. A., and later captain of cavalry during the Civil War; died, January 22.

Theophilus W. Bennett, Long Beach, Calif.; College of Physicians and Surgeons, Keokuk, Iowa, 1877; aged 67; formerly of Lenox, Iowa, and for three terms a member of the Iowa state senate; died, February 3.

Joseph Antoine Beaudry, Montreal; University of Victoria College, Cobourg, Ont.; 1878; aged 67; inspector general of the superior council of hygiene of the province of Quebec since 1888; died, Dec. 2, 1919.

Jeptha Dillon, Fillmore, Calif.; Medical College of Ohio, Cincinnati, 1873; aged 75; once president of the Greenwood County (Kan.) Medical Society, and a practitioner of Eureka; died, February 9.

Loren L. Gray, Powersville, Mo.; Northwestern Medical College, St. Joseph, Mo., 1884; aged 58; a member of the Missouri State Medical Association; died, Dec. 20, 1919, from acute pancreatitis.

Henry Beauregard Disharoon, Roanoke, Ala.; College of Physicians and Surgeon, Baltimore, 1885; aged 59; a member of the Medical Association of the State of Alabama; died, February 11.

Charles A. Wakeman, Tawas City, Mich. (license, Michigan, five years' practice, 1900); aged 66; died at Pinconning, Mich., January 25, from dilatation of the heart due to bronchial asthma.

William J. Willim, Wynne, Ark.; College of Physicians and Surgeons, Keokuk, Iowa, 1882; aged 66; formerly a practitioner of Joplin, Mo., and physician of Jasper County; died, January 21.

John Stanley Thibaut, Donaldsonville, La.; Tulane University, New Orleans, 1883; aged 60; vice president of the Bank of Ascension; died in Touro Infirmary, New Orleans, February 12.

* Indicates "Fellow" of the American Medical Association.

Robert John Gordon, U. S. I. S., Gordon, Wis.; George Washington University, Washington, D. C., 1917; an Indian physician; aged 25; died, February 10, from pulmonary tuberculosis.

John William MacKay, Calgary, Alberta; Western University, London, 1907; aged 39; captain, C. A. M. C.; died, Oct. 25, 1919, from pulmonary embolism following appendectomy.

James T. Douglas, Ferguson, Mo.; Washington University, St. Louis, 1859; aged 84; a member of the Missouri State Medical Association; died in St. Louis, Nov. 29, 1919, from uremia.

George Levi Alexander, Milwaukee; Hahnemann Medical College, Chicago, 1888; aged 54; a member of the staff of Hanover Hospital; died, February 13, from cerebral hemorrhage.

John Wesley Ishmael * Winchester, Ky.; Jefferson Medical College, 1872; aged 70; president of the medical staff of Clark County Hospital; died, February 6, from pneumonia.

James H. Shepperd, Peoria, Ill.; Meharry Medical College, Nashville, Tenn., 1899; aged 54; captain, M. C., Ill. N. G., and assigned to the Eighth Infantry; died, February 10.

Earl C. Rieger * Kansas City, Mo.; University Medical College of Kansas City, Mo., 1906; aged 41; also an attorney; died, January 28, from pneumonia following influenza.

Edgar Parker Hershey * Denver; Jefferson Medical College, 1888; aged 58; once president of the Denver and Arapahoe County Medical Society; died, January 27.

Anna T. Dunn Roe Murphy, Detroit; Michigan College of Medicine and Surgery, Detroit, 1894; a member of the Michigan State Medical Society; died, February 14.

Hannah C. Reinhold, Williamsport, Pa.; State University of Iowa, Homeopathic College of Medicine, Iowa City, 1892; aged 64; died, February 11, from pneumonia.

Robert C. Forsyth * Kirkwood, Mo.; Washington University, St. Louis, 1902; aged 40; died in St. Luke's Hospital, St. Louis, February 8, from influenza.

Jerome A. Heath, Cleveland, University of Wooster, Cleveland, 1884; aged 60; one of the founders of St. Clair Hospital, Cleveland; died, Dec. 10, 1919.

John Paul Golden, Pittsburgh; University of Pittsburgh, 1888; aged 56; a member of the Medical Society of the State of Pennsylvania; died, February 7.

Zenas Cather Clayton, Chicago; Kansas City Hospital College of Medicine, Kansas City, Mo., 1885; aged 62; died, February 10, from heart disease.

William Gage Potter, South Dartmouth, Mass.; University of the City of New York, 1888; aged 55; died, Dec. 18, 1919, from tuberculosis of the lungs.

Irvine Ketcheson Mott, Cincinnati; Pulte Medical College, Cincinnati, 1883; aged 59; died in Covington, Ky., February 7, from cerebral hemorrhage.

George Maurice Stelzleni, St. Louis; Washington University, St. Louis, 1880; aged 58; died, February 14, from pneumonia following influenza.

William John Martin, Philadelphia; Jefferson Medical College, 1881; aged 61; a practitioner of dentistry for many years; died, February 12.

Cincinnatus C. Maddox, Alpharetta, Ga.; Atlanta (Ga.) Medical College, 1880; aged 61; died in a sanatorium in Atlanta, January 6.

Andrew B. Spinney, Ionia, Mich.; Homeopathic Hospital College, Cleveland, 1859; aged 84; an itinerant practitioner; died, February 7.

Robert Edward Bradsher * Marmaduke, Ark.; Memphis Hospital Medical College, 1904; aged 43; died, February 8, from pneumonia.

Louis Kaelin, Louisville, Ky.; Kentucky School of Medicine, Louisville, 1894; aged 62; died, Dec. 29, 1919, from bronchiectasis.

Alexander Franklin Durham, Sparta, Ga.; Jefferson Medical College, 1887; aged 54; died, January 30, from valvular heart disease.

Nelson Gregory Hall, Nut Plains, Conn.; Yale University, New Haven, 1860; aged 86; died, January 15, from senile debility.

Hal Augustine Hardeman, Melrose, Texas; Atlanta (Ga.) Medical College, 1891; aged 60; died, February 3.

Charles Frederick Sporman, Headland, Ala.; University of Alabama; Mobile, 1886; died, January 31.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

GREEN'S DROPSY REMEDY

For some years THE JOURNAL has been receiving inquiries regarding "Green's Dropsy Remedy," put on the market by "Dr. H. H. Green's Sons," Atlanta, Ga. It is now sold by Dr. Thomas E. Green, who claims to be a successor to "Dr. H. H. Green's Sons," and it now comes from Chatsworth, Ga.

The business is a mail-order one. As with others of a similar type, the advertising claims in the past few years have undergone the usual modifications from the "lie direct" to the "lie with circumstance" as the following quotations—italicized by us—will show:

OLD CLAIMS

"Dr. H. H. Green's Sons Cure Dropsy In All Its Various Forms."

"Have cured many thousand cases after having been pronounced utterly hopeless by eminent physicians."

"The Only Reliable and Successful Dropsy Treatment Known."

"We have cured thousands of seemingly hopeless cases."

"We have cured many patients after the family doctor had said there was no hope for recovery."

RECENT CLAIMS

"Dr. H. H. Green's Sons Treat Dropsy In All Its Various Forms."

"Have relieved many thousand cases after having been pronounced almost hopeless by eminent physicians."

[Statement eliminated.]

"We have relieved hundreds of seemingly hopeless cases."

"We have entirely relieved many patients after the family doctor has said there was little hope for recovery."

The methods by which the Green concern gets in touch with prospective purchasers are the usual ones: Advertisements in the cheaper grades of magazines and in not-too-particular newspapers. In some cases advertising booklets have been mailed to small towns in various parts of the country addressed to "The Mayor or Any Minister of the Gospel." Those who answer the advertisements (which offer "a free trial treatment") are sent a question blank which must be filled in and returned before the sample is sent. With the sample is a statement to the prospective purchaser to the effect that if he wishes to take a course of "regular treatments" these will cost \$10 or \$15 each, as the case may be.

The "treatment" itself comes in the form of large black balls or boluses which when first sent out are moderately soft but become harder on keeping. One treatment seems to consist of six large boluses and six small ones—even the small ones are heroic in size. In addition, some purchasers receive "Tonic Tablets." The purchaser is directed to take "a large ball dissolved in a little water at nine o'clock at night and a small ball at midnight." At six o'clock the next morning and every hour thereafter until eleven a. m. a substantial dose of Epsom salt is to be taken in quantities sufficient to create a large number of bowel movements. This dosing is to be repeated "every other night and day until all dropsical accumulation is removed from the system"! The boluses and tonic tablets were examined by the Association's chemists who have reported as follows:

CHEMISTS' REPORT

"One 'treatment' of Green's Dropsy Remedy, consisting of large balls or boluses, small balls or boluses and 'Grey Tonic Tablets' was examined. The small balls and the large balls appear to be of the same composition. The masses are brownish-black in color. When first received they were of about the consistence of a stiff pill mass but they became harder on keeping. Iodids, alkaloids, emodin-bearing drugs and magnesium sulphate were absent. The boluses yielded about 4.2 per cent. of ash in which were found iron, calcium, a sulphate and a phosphate, each in small amounts. Microscopic examination revealed the pres-

ence of a vegetable drug which appeared to be powdered squill. The preparation contained a considerable amount of dark colored extractive but this could not be identified. It was darker in color than would be expected from squill. It resembled licorice extract but tests for glycyrrhiza were negative. Reducing sugars were present.

"Examination of the 'Grey Tonic Tablets' failed to reveal any potent drug, except an iron salt, equivalent to about 2.65 per cent. of iron. The iron was present in both the ferrie and ferrous condition, which would warrant the suspicion that dried ferrous sulphate is the salt used in the manufacture of the tablets. Large quantities of starch and calcium sulphate were present. Alkaloids, iodids and emodin bearing drugs were absent.

"To sum up: The boluses, large and small, appear to contain powdered squill as the chief medicinal ingredient. The tablets contain an iron salt, probably dried ferrous sulphate, as the chief medicinal ingredient."

Obviously there must be no small amount of danger for a person in a dropsical condition to dose and drastically purge himself. Yet, as in all cases of self-dosing, accidents that might follow would seldom be reported and in many instances might be suppressed by relatives who shunned publicity. One physician has reported that he had seen two patients in a state of collapse after taking the Green treatment—whether from the purging or the Green nostrum he was unable to say. Some years ago a newspaper reported the sudden death of a woman following the Green treatment but the coroner's inquest failed to elicit sufficient evidence to place the responsibility for the death on the Green

Facsimiles (reduced) of old and more recent advertising.

product. No necropsy or analysis was made in the case. In the case of another woman who also died suddenly while taking the Green dropsy cure, the local health office sent Green a death certificate advising him that the family declared that he was treating the woman at the time of her death. The only information given in the certificate as returned was the name and age of the woman and the statement that the primary cause of death was "Heart and Kidney trouble producing Anasarca."

Whatever part the Green "cure" may have played in these cases, one thing is certain: The product is one that has no legitimate place among home remedies. The public does not realize that dropsy is a symptom and not a disease and usually a symptom of serious import. For a person suffering from either heart or kidney trouble to attempt to treat himself with powerful drugs for the dropsical condition that may follow is the height of unwisdom. The idea that such serious conditions can safely and intelligently be handled on the mail-order plan without any physical examination of the patient or even seeing the patient is, of course, preposterous.

Deaths from Tuberculosis.—According to official census figures the death rate from all forms of tuberculosis in Wilmington, N. C., had fallen from 272.3 in 1912 to 180.9 per hundred thousand in 1917, which is the last year for which federal figures are available. This annual saving averages twenty-three lives a year for five years from tuberculosis alone. Capitalizing each life at the very low estimate of \$2,000, shows an annual saving of \$46,000, or \$230,000 for the five years, which is an amount greatly in excess of what was contributed both for Red Cross Christmas seals and the health department.—*Our Communal Health*, October, 1919.

Correspondence

CONDITION OF THE OLIVES RESPONSIBLE FOR THE NEW YORK OUTBREAK OF BOTULISM

To the Editor:—In an editorial entitled "Botulism from Ripe Olives" (*THE JOURNAL*, Feb. 21, 1920, p. 530), the following sentence appears relative to the physical characteristics of the olives responsible for the recent outbreak of botulism in New York City, a report of which is printed in the same issue of *THE JOURNAL*: "Although a half bottle of ripe olives, probably the one that contained the toxin, was found in the home of the victims, no statement is made about the physical condition of these olives." The following information might well have appeared in the article:

The three olives received for examination were in a turbid, brownish tinged with red, watery fluid which was very difficult to see through. There was a slight flocculent precipitate in the bottom of the bottle. The olives themselves were lighter in color than ordinary ripe olives, having a tan, buff, almost straw color. They were somewhat spotted, each olive having several distinct black spots in it which stood out sharply from the lighter, general color of the olive, possibly areas from which the normal black color had not yet faded. In addition there were small, whitish, flocculent, irregular, lichen-like spots, giving somewhat the impression of being deposited on the surface, scattered irregularly over each olive. They had lost the shining luster usually seen in normal ripe olives. In consistency they were softer and not so firm as normal ripe olives. They were not, however, actually mushy, and could be lifted out of the bottle on the point of a knife.

The odor, in addition to that of ripe olives, had a weak but apparently quite definite putrefactive tinge. There was no suggestion of butyric acid. There was considerable controversy in the laboratories in New York and Boston as to whether the odor present in the olives could be considered characteristic enough to be of protective value to the average individual. Among those men who had worked with *B. botulinus*, and particularly those who had handled the olives from the Canton and Detroit outbreaks, there seemed to be no question as to the definiteness of the odor. Some of these men were so sure of their sense of smell that they ate olives from bottles of the same brand which were being investigated and which did not hold the suspicious odor. On the other hand, laboratory workers who had not had particular experience with *B. botulinus* were very skeptical and not inclined to feel that the average individual would have refused to eat these particular olives on account of a disagreeable odor. In our own laboratories, even among men who had frequently smelled *B. botulinus* cultures in various mediums, there was considerable controversy.

At present, almost seven weeks after the outbreak, these olives present the same picture, much accentuated in every way. They are now light tan, the black spots are not so numerous (owing possibly to gradual loss of the normal black color as the process of putrefaction progresses), the liquor is perhaps more turbid and deeper in color than it was, and the flocculent precipitate is more abundant. The liquor is covered with a thin, greenish mat of mold. The whitish, lichen-like spots are more numerous than before. The olives are now so mushy that they cannot be lifted on the point of a knife. The odor is much less marked than seven weeks ago. (The bottle has been tightly corked, though not sealed.) It is now a sweetish, spicy, weakly pungent odor, suggestive, but not definitely putrefactive, in character. There is no consensus as to what may be called a "characteristic" botulinus odor. In fact, there is a growing belief that *B. botulinus* does not have a "characteristic" odor any more than other anaerobic putrefactive organisms have. An odor of putrefaction may perhaps, to a greater or less degree, be present, but other than that it seems unwise to say more at present.

DWIGHT L. SISCO, M.D., Boston.

A CABINET OFFICER FOR SUPERVISION OF NATIONAL HEALTH AND EDUCATIONAL PROBLEMS

To the Editor:—Medicine has never been so efficient, so well organized or so thoroughly appreciated as it is now. The power to exercise our knowledge of disease and its control, as shown by our care of the millions engaged in warfare, the use of vaccines, serums and antitoxins by the wholesale, and the results of the surgical treatment of wounds and the prevention of infection, has given the profession a public recognition never before accorded it. This resulted from the enforced medical organization endowed with military authority and opportunity. The examination and supervision of the recruits gave wonderfully valuable information concerning both the lack of supervision of the health of young persons engaged in the occupation of education, and the lack of supervision of education. In our country's rapid commercial advancement we have been glad to use immigrant labor whose cost of production fell on Europe, and little attention was given to the health problems of labor.

In a general way, medical organizations of the past have been wont to criticize the attitude of both the government and the public concerning public health problems, as well as their failure to appreciate the necessity of establishing national standards of medical education and control of medical practice. I have always had a firm conviction that the reward of labor is in a fairly just measure in proportion to what is given; and it is undoubtedly true that medical standards are appreciated by the public as representing the average of medical knowledge so far as the public has had the opportunity to learn of them. Medical men have done little in local or state civic affairs, especially in lines in which they are competent to give advice, that is, education and public health problems. There should be a physician on every school board; also, a member of the city council should be a physician, and local medical organizations should actively support the public health officials. The fact is that the profession is only now ready to do its part in our civic life by reason of these very standards, which have been made as a result of military control of medical affairs and their application. The rapid evolution and advance of medicine in the last few decades has only now made this possible. I feel, then, that there should be no unjust criticism of the President for not appointing on the industrial investigating committees a single physician, large as the personnel have been, although in these conferences there were serious problems of health to be considered in its relation to hygiene, housing, child welfare, food and education, conditions which are properly medical problems.

We now have the greatest power, although it is intangible, which has ever existed, and which may be turned to our aid: that is, the psychic condition that has resulted from the mental concentration of the civilized people of the whole world on war and its problems for a period of five years without a day's intermission. The after-war condition as a result of the mental strain leaves the whole world in a chaos of disorganization and mental instability. In the individual we would call the condition a neurosis. We should take advantage of this psychic condition in our reconstruction problems along educational and public health lines, which are now matters of general discussion in this country, so as not only to serve the people of coming generations but also to maintain the present prestige of medicine. The many bills now before Congress in which the real motive is a health problem show the deep public concern.

In Washington, where medical standards and health problems should be representative. I found after nearly two years' residence that, so far as the government is concerned, medical affairs are most incoordinate. Laws controlling health problems, which have divided medical affairs among every cabinet bureau and numerous committees and boards, numbering about eighteen in all, have been passed as riders on necessary bills and appropriations. These boards seriously overlap in the conception of their functions, and there is apparently no way of securing coordination, although in their general activities much good is accomplished. The

largest service is the Public Health Service under the Treasury Department; under Labor is Child Welfare, Prevention of Industrial Accidents and special boards; under the Department of the Interior is the care of the insane, not otherwise looked after and the Board of Indian Affairs; under Commerce, all statistical records relating to health and mortality, acceptable from about thirty-four states; under Agriculture, the Food and Drugs Act. I mention these few to show the condition. Rather lavish appropriations are made by the government for all the hospitals in Washington, and an equal amount by the board of the District of Columbia. All in all, a sufficient amount is thus expended locally to make government officials feel that they are doing much for the care of public health. Congress stands ready to help in the emergency of sickness like the recent influenza epidemic, when half a million dollars was appropriated for its control, it being much easier to give than to spend wisely.

With the high cost of labor and its rapid turnover, industrial organizations have taken every precaution to look after the health, housing, child welfare and social life of their industrial workers, to them an economic problem. The greatest industry of our country today is education, and we have learned from the examination of our draft recruits that there has been little care in general given to child welfare or to the protection of the health of the youth of our country thus engaged. The national need today for Americanism is intelligent supervision, with authority, of both education and public health, and the most important problem is that of health. While it may not be possible to secure a bureau chief for each, it should be possible to secure an official who would have supervision of health in the United States and coordinate the multitude of health problems now existing, as well as having the supervision of education.

CHARLES H. MAYO, M.D., Rochester, Minn.

DESTRUCTION OF B. BOTULINUS TOXIN BY BOILING RIPE OLIVES

To the Editor:—A number of deaths in various sections of the country have been attributed to poisoning due to toxin formed by *Bacillus botulinus* in canned ripe olives. This toxin is readily destroyed by heat. The flavor of ripe olives is not materially affected nor is the texture destroyed if the olives are boiled for fifteen minutes in the liquid in which they are preserved. This amount of heat is sufficient to destroy the toxin, and the product can be eaten with safety. This method will also exaggerate the odor of decomposition and tend to discourage the serving of olives partially spoiled. In every instance the olives were said to have a "queer odor." This is a simple method, easily applied, and would seem to eliminate the danger from eating ripe olives.

M. GRUNFIELD, Albuquerque, N. M.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

REMOVAL OF TATTOO MARKS

To the Editor:—During the war, thousands of Armenian girls and children were taken by Turks and Kurds, and their faces tattooed. Now some of them have been brought back as refugees to their parents with their faces bearing these ugly tattoo marks. Please describe a method of treatment for removing these marks without leaving any scar.

DR. M. HOVNERIAR, Aleppo, Syria.

ANSWER.—Replies to this question have appeared several times in Queries and Minor Notes. The methods of Variot and Brault have been recommended. The principle in each is to excite an inflammatory process by means of chemical irritants so as to cause destruction of the superficial layers of skin.

Variot uses as an irritant silver tannate produced by tattooing in a strong solution of tannin and rubbing a silver

nitrate pencil over the spot until it is blackened by the formation of silver tannate.

Braut removes the marks by tattooing the surface with a solution of 30 parts of zinc chlorid to 40 parts of water. A slight crust forms after these applications, the spontaneous removal of which after two weeks is followed by a pink cicatrix which gradually becomes of normal color.

The method is also described in practically all textbooks on diseases of the skin.

MALLORY'S EOSIN AND METHYLENE BLUE TISSUE STAIN —VLEMINCKX' SOLUTION

To the Editor:—Please supply me with (1) the formula and technic for Mallory's eosin and methylene blue tissue stain; and (2) the formula for Vleminckx' solution. I find frequent references to these items, but am unable to find the formulas and technic in any of my books.

MILES J. BREUER, M.D., Lincoln, Neb.

ANSWER.—1. A formula and technic for the eosin and methylene blue tissue stain may be found in Mallory, F. B., and Wright, J. H.: *Pathological Technique*, Ed. 6, Philadelphia, W. B. Saunders Company, 1915, p. 328.

The instructions given there are as follows:

Fix in Zenker's fluid.

Stain paraffin section in 5 per cent. aqueous solution of eosin for twenty minutes or longer. To get a deeper eosin stain place the sections in the paraffin oven for from fifteen to twenty minutes.

Wash in water to get rid of the excess of eosin.

Stain in Unna's alkaline methylene blue solution diluted one part to four or five parts of water for ten or fifteen minutes.

Wash in water.

Differentiate and dehydrate in a dish of 95 per cent. alcohol, keeping section in motion to decolorize uniformly. Control results under the microscope; when pink color has returned to the section and the nuclei are still deep blue, finish dehydration quickly with absolute alcohol.

Xylene.

Xylene balsam.

For celloidin sections use 95 per cent. alcohol, blot, and pour on xylene; repeat the last two steps until the specimen is clear.

Unna's alkaline methylene blue solution consists of methylene blue, one part; potassium carbonate, one part; water, 100 parts. For staining, the solution should be diluted 1:10 or 1:5; ripening the solution for a week improves the results.

2. The formula for Vleminckx' solution was published in THE JOURNAL, Jan. 24, 1920, p. 268.

STANNOXYL: A TIN PREPARATION

To the Editor:—I am very anxious to know whether tin or stannous oxide (SnO) has or has had any place among useful drugs. I have seen such a prescription given in the treatment of mucous colitis, and would be very glad to learn what its use may be.

CARLOS MANUEL GARCIA, M.D., Havana, Cuba.

ANSWER.—Recently, on the assumption that tin workers are less troubled with boils than the average person, two French investigators proposed the use of tin compounds in the treatment of staphylococcal infections. Based on their work, a proprietary preparation—Stannoxyll—has been placed on the market which is claimed to be "composed of stannous oxide and specially purified metallic tin." Absurd claims are made for the product; for instance: "We have no hesitation in offering STANNOXYL—in Tablets or Cachets—as the only true specific for diseases of Staphylococcus origin." The available evidence is unconvincing and in no way warrants such exaggerated statements.

Industrial Physician.—The industrial physician of the future must be able to interpret industrial processes, understand the operation of mechanical appliances, size up the human requirements for filling a certain job, make scientific studies of the hazards of occupations, make certain that proper working conditions are provided for the industrial population, and interpret these findings in terms of increased production, decreased labor turnover, and healthier and happier workers. He should also be able to tune up the home, community and industrial environment so that each would bear its part of carrying forward the great commercial life of the Nation.—F. L. Rector: *Public Health Rep.*, Jan. 9, 1920.

RHODE ISLAND: Providence, April 1-2. Sec., Dr. Byron U. Richards, State House, Providence.

WEST VIRGINIA: Charleston, April 13. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

Oregon July Examination

Dr. Frank W. Wood, secretary of the Oregon State Board of Medical Examiners, reports the written examination held at Portland, July 1-3, 1919. The examination covered 11 subjects and included 90 questions. An average of 75 per cent. was required to pass. Twenty-seven candidates were examined, all of whom passed. The following colleges were represented:

College	PASSED	Year Grad.	No. Licensed
Bennett College of Eclectic Med. and Surg.	(1906)		1
Rush Medical College	(1919)*		1
University of Illinois	(1913)		1
Keokuk Medical College	(1895)		1
College of Physicians and Surgeons, Baltimore.....	(1891)		1
Harvard University	(1916)		1
Kansas City University of Phys. and Surgs.	(1919)		1
University Medical College of Kansas City	(1908)		1
Lincoln Medical College	(1917)		1

Book Notices

REPORT ON THE PRESENT STATE OF KNOWLEDGE CONCERNING ACCESSORY FOOD FACTORS (VITAMINES). Medical Research Committee, Special Report Series, No. 38. Boards. Pp. 103, with illustrations. London: His Majesty's Stationery Office, 1919.

This gives an excellent summary of our knowledge of these unknown essential substances, which go by various names and are concerned in different clinical conditions. A sentence selected from the introduction emphasizes our need for future investigation in this field, and expresses well the feeling of all investigators of this topic: "The practical importance of the facts will not be understood unless it be recognized that a deficiency in food, which when complete or extreme leads to actual disease, may, when only relative, be responsible for ill health of a vague but still important kind." The accessory food factors are classified according to the division made by McCollum, that is, fat-soluble A and water-soluble B, evidence being set forth that the latter is identical with the antiberiberi factor. In addition, the antiscorbutic vitamin is given an equally prominent place as a third distinct factor. The chemical and resistant properties and the distribution among foodstuffs of each are discussed. In the table on the protective value of various foodstuffs against scurvy, the tomato is not included. Since Hess has demonstrated the value of this food as an antiscorbutic, it ought to appear in such a table. Two instructive chapters on the application of experimental work to the practical problems of adults' and infants' diets give many useful data for the dietitian. Rickets is classified as a deficiency disease in which the antirachitic factor has a possible identity with the fat-soluble A factor. Pellagra is likewise considered a deficiency disease, but one in which the underlying cause is more or less undetermined. The appendix is a guide for those who wish to know what foods are rich in the accessory food factors, and gives instructions on the prevention of the well-known deficiency diseases.

PRÄKTIKUM DER MEDIZINISCHEN CHEMIE. Einschliesslich der Forensischen Nachweise für Mediziner und Chemiker. Von Dr. Sigmund Fränkel, Professor der Medizinischen Chemie an der Universität in Wien. Paper. Price, 18 marks. Pp. 439, with illustrations. Berlin: Urban & Schwarzenberg, 1918.

By those familiar with Fränkel's "Arzneimittelsynthese," the Praktikum der medizinischen Chemie will be examined with interest. The book aims to be sufficiently comprehensive to be used as a guide book in the instruction of physicians and chemists who desire more than usual knowledge of pure and applied medicinal chemistry. It contains methods for qualitative and quantitative inorganic analysis, the detection and analysis of many organic substances used in medicine, and the methods used in physiologic, pathologic and forensic chemistry. In a work of less than 450 pages the subdivisions in such a comprehensive task must necessarily be brief; yet no subject important to the field appears to have been omitted. The methods are given without much discussion concerning the interpretation of results, the latter being left to the teacher and analyst using the book. No bibliography is given, although usually the methods are described under the author's name. The work should prove useful to the chemists of municipal and public health laboratories, but will not be of much value to practicing physicians.

ANAPHYLAXIS AND ANTI-ANAPHYLAXIS AND THEIR EXPERIMENTAL FOUNDATIONS. By A. Besredka, Professor at the Pasteur Institute. Preface by Dr. E. Roux. English Edition by S. Roodhouse Gloyne, M.D., D.H.P., Pathologist, City of London Hospital for Diseases of the Chest, Victoria Park. Cloth. Price, \$2.25. Pp. 143. St. Louis: C. V. Mosby Company, 1919.

For a monograph of 130 pages this book is abundantly introduced, there being four introductions, one each by Vaughan, Roux, the author and the translator. It is principally valuable, as summarizing the important work of Besredka and his associates on anaphylaxis up to a time shortly before the war. There is a brief chapter by the translator which purports to bring the work up to date, but

it is by no means complete or adequate in this respect. It is far from being a full statement of our present knowledge of this subject but does give much information in a very readable form. Besredka is among those who hold that there is no anaphylactic poison or anaphylatoxin, believing that the antibody makes possible the entrance of the antigen into certain nerve cells, where it causes the observed disturbances. He discusses at particular length the resistance conferred to man or animals by injection of a nonfatal dose, for which condition he uses the term "antianaphylaxis," although the term "desensitization" is to be preferred. The work is attractively written and well translated, although there are several errors to be noted.

DIGEST OF COMMENTS ON THE PHARMACOPOEIA OF THE UNITED STATES OF AMERICA AND ON THE NATIONAL FORMULARY FOR THE CALENDAR YEAR ENDING DECEMBER 31, 1915. By A. G. DuMez. Hygienic Laboratory Bulletin No. 118. Paper. Price, 35 cents. Pp. 456. Washington: Government Printing Office, 1919.

DIGEST OF COMMENTS ON THE PHARMACOPOEIA OF THE UNITED STATES OF AMERICA AND ON THE NATIONAL FORMULARY FOR THE CALENDAR YEAR ENDING DECEMBER 31, 1916. By A. G. DuMez. Hygienic Laboratory Bulletin No. 119. Paper. Price, 20 cents. Pp. 316. Washington: Government Printing Office, 1919.

Reviews of this annual volume have appeared in THE JOURNAL from time to time. The digests were formerly prepared by M. I. Wilbert, who died in 1916. The interruption caused by his death and the selection of a successor delayed the appearance of the 1915 volume until now, so that the volumes for 1915 and 1916 have appeared simultaneously. A part of the manuscript on the former volume had been prepared by Mr. Wilbert, and Dr. DuMez has continued the compilation according to the system inaugurated by his predecessor. The digests contain not only the abstracts of criticisms that have been made on drugs that are described in the U. S. Pharmacopoeia and National Formulary, but also comments on all kinds of substances that are used in medicine or which are likely to be so used. The abstracts are unbiased, commendatory and condemnatory comments being given equal prominence. The physician or pharmacist who owns the work has at his command the consensus on the therapeutic status of drugs, as well as their market quality, tests for their identification and purity, and methods for making their preparations. Within certain limits for free distribution, copies may be obtained by application to the Surgeon-General of the Public Health Service, Washington, D. C. They may also be obtained at a nominal price from the Superintendent of Documents, Washington, D. C.

NERVOUS AND MENTAL DISEASES. By Archibald Church, M.D., Professor of Nervous and Mental Diseases, Northwestern University Medical School, Chicago, and Frederick Peterson, M.D. Ninth edition. Cloth. Price, \$7 net. Pp. 949, with 350 illustrations. Philadelphia: W. B. Saunders Company, 1919.

The authors state that no radical changes have been made in the new edition, and that they are suspending judgment concerning certain advanced views until time and experience have determined whether or not these matters are to become established. The subjects of general paresis and traumatic insanity have been rewritten. There is brief mention of the newer views concerning lethargic encephalitis. The work is a standard text of well merited popularity.

THE OPERATIVE STORY OF GOITER. The Author's Operation. By William S. Halsted. The Johns Hopkins Hospital Reports, Volume 19, Fasciculus 2. Price, \$3.50. Paper. Pp. 257, with illustrations. Baltimore: Johns Hopkins Press, 1919.

As might be surmised from a glance at the title, in this book is presented a historical account of the development of the operative treatment of goiter. It brings out in a striking manner the enormous influence of the introduction of general anesthesia, and with it a more deliberate method of operating; of the development of aseptic technic, and of a third factor of which little is written, namely, the invention of the artery clamp. Hemorrhage, with or without infection, was the cause of death in most of the early strumectomies, and it might almost be said that the invention of the artery clamp made goiter operations possible. To the shallow faddist who gets his information from the advertising pages of his med-

ical journals, and whose chief aim therefore is to be "up to the minute," this book will make no appeal; to the earnest student of surgery, to the man who appreciates broad, deep foundations, to the real builders in medicine, it will afford inspiration to increased effort and better work.

Social Medicine and Medical Economics

THE PHYSICIAN'S BURDEN UNDER WORKMEN'S COMPENSATION ACTS

M. L. HARRIS, M.D.
CHICAGO

The physician, as a rule, gives too little attention to the affairs of life outside his own line of work. Even when the matter is one that concerns him more or less directly, he seldom gives it sufficient thought or study to protect his own interests, and he often submits to injustice uncomplainingly rather than take the time and trouble to assert his rights.

This characteristic indifference of the profession is well known to legislative bodies, and as a result, when economic questions in which the physician should be interested are before these bodies for legislative action, the profession receives little or no consideration and, in fact, is often not even consulted. I need not now take the time to analyze the reason for this persistent indifference of the profession to matters of this kind, but will simply state that in many instances it has resulted in great detriment to the welfare of the people as a whole and to the medical profession in particular.

THE WASHINGTON WORKMEN'S COMPENSATION ACT

A good illustration of what amounts almost to contempt of the medical profession is shown in the first workmen's compensation act which was passed by the state of Washington in 1911. As is well known, workmen's compensation laws were enacted for the purpose of providing some compensation to workmen for injuries arising out of and in the course of their employment.

The first thing that an injured person needs in the way of compensation is medical attention for his injuries; but in the Washington act, not only was no provision made for paying a physician for his services to the injured, but many onerous duties were thrust on him which he was obliged to perform gratuitously. Naturally, the physician is the first person who is usually called when a workman is injured, and under the law he was required to make out an elaborate report of the case on blanks furnished for the purpose and send these to the industrial commission. On the blank form the following note was printed:

This form should be made out and forwarded to the office of the commission in Olympia as soon as the surgeon has made such careful examination as will enable him to make an intelligent report of the case. No fee is paid for making out this blank, but the commission respectfully urges the cooperation of attending physicians in getting the real facts of each case before it. N. B. Your patient cannot receive any compensation from the state until this form is received and passed upon by the chief medical officer of the commission.

How gently the physician is sandbagged into making out his report for nothing: no report, no money for the injured workman—the inference, of course, being: no money for the patient, no money for the physician. When the patient was discharged by the surgeon, the surgeon was obliged to make out another elaborate report and send it to the office of the commission. In this report, in addition to other facts, the physician was required to state the cost of medical and surgical treatment, cost of medicine, medical and surgical supplies, cost of crutches and apparatus, hospital charges, ambulance charges, and cost of nursing. There was still

another "form of surgeon's special report with charts," to be made out and sent to the commission; and finally, in case of death, the physician was obliged to fill out and file "form of proof of death by physician." In addition to his duty as a physician, the law stated:

... and it shall be the duty of the physician to inform the injured workman of his rights under this act and to lend all the necessary assistance in making out his application for compensation and such proof of other matters as required by the rules of the department without charge to the workman.

Commenting on this last section, the industrial board naively remarked that what the physician does is simply a duty which he owes to the state; hence no payment is allowed therefor. The physician must not only take care of the injured workman, but under the act he was made the agent of the commission for the purpose of collecting and furnishing it with information, and was made the legal adviser of the injured workman and had to inform him of his rights under the act and "assist in making such proof of other matters as required by the rules of the department," for all of which services he was not only not allowed any compensation by the state, but was prohibited from making any charge to the workman for the simple reason that it was all a duty which he owed the state.

In order that physicians might not delay in performing their "duty to the state," the law provided that any person who fails to furnish the information and reports required by the commission shall be deemed guilty of a misdemeanor, the penalty for which is imprisonment in the county jail not to exceed ninety days or by fine not to exceed \$250. This would certainly be amusing were it not a fact and were it not of such vital importance to the economic welfare of the profession. When did it become a "duty which the physician owes the state" to work for nothing? When did it become a duty of physicians to give legal advice to injured workmen and to assist them in making out their claims for compensation and to assist them in furnishing proof of such other matters as may be necessary, and all without recompense? It seems that in the state of Washington it was thought that the physician owed it to the state to work for nothing, and was encouraged to do it under a penalty of ninety days in the county jail or a fine of \$250. If the physician is only meek and lowly enough he will soon have sufficient duties and obligations thrust on him by the state so that he will eventually be able to work his way into the state poorhouse. Such an absurd law as the Washington workmen's compensation act of 1911 never could have passed had the physicians been alert to their own welfare. It took some years to change that law so that the medical profession was given some consideration.

PRINCIPLE UNDERLYING WORKMEN'S COMPENSATION LAWS

While no other state has passed such a shameful workmen's compensation law as the Washington act of 1911, in the majority of the states the physician under workmen's compensation acts is meekly performing "the duty which he owes to the state" by caring for injured workmen for nothing. The fundamental principle underlying workmen's compensation acts is that the industry should bear as part of the cost of production the expense incident to injuries to workmen arising out of and in the course of their employment. In other words, the workman is to be looked on as a part of the general machinery of the industry and, like any other piece of machinery when injured, he should be repaired if possible, the cost of the repairs to be charged to general operating expense. The only difference between the human machine—the workman—and the inhuman machine is that the human machine loses his earning power while laid up during repairs, but must live at an expense to himself; hence he is allowed as part compensation a certain percentage of the wages he was earning when injured to tide him over until

he is again able to earn as before; or in case he is permanently incapacitated, until a predetermined amount has been paid to him.

It will be granted that the principle underlying workmen's compensation laws is sound. All state legislative bodies in enacting such laws recognize the principle that the burden of caring for accidental injuries to workmen arising out of and in the course of their employment is a legitimate expense of the industry chargeable to production. Such being the case, why is it that the majority of the workmen's compensation acts, which are based on the principle just announced, deliberately take a large part of the burden off the industry or the employer, and put it on the medical profession? Why should the medical profession, which has nothing to do with production, be compelled by law to assume a large part of the expense of caring for injured workmen, which expense, the same law announces on principle, should be borne by the industry or the employer? If the principle is correct, then the employer should pay all the expense and not a part of it while the physician pays the balance. How is it that the physician is obliged to assume without remuneration a large part of the expense of caring for injured workmen under workmen's compensation acts?

HOW IT WORKS OUT

In defining the amount and terms of the compensation to be paid, the acts state that the injured workmen shall receive medical and surgical care, including drugs, medicines and surgical appliances, hospital care and nursing, however, not to exceed \$100, or \$200, as some states have it. Any intelligent person knows that \$100 or even \$200 will not pay hospital and nursing bills and the expense of drugs, medicines and surgical dressings and appliances, and leave anything for the physician in a serious injury requiring one or more surgical operations and several weeks' careful attention. What happens is something like this:

A workman is injured, and a physician is called and told to do everything he can for the patient. It is necessary to have him removed to a hospital, and perhaps a serious operation must be performed, such as an amputation of a leg or, what even is more difficult, the repair of a bad compound fracture with the necessary subsequent care, etc. The hospital has its bills paid weekly, and after a time the physician sends in a bill, possibly, on account. He shortly receives a letter from the employer, who seems quite grieved to think that he should be sent a bill, for he has already paid the bills at the hospital, amounting to so and so much, which of course he thought included medical and surgical services. When informed to the contrary, he comes back with the statement that he has already paid all that the law requires, namely, \$100 or \$200, as the case may be, and has therefore discharged his liability and that the physician will have to look to the injured person for his bill. As the man is out of employment for many weeks or months on account of his injury; as the cash compensation which he received was barely sufficient to keep his family in food while he was laid up; as he is back in house rent and other necessary living expenses, and as he was working under the compensation act which he supposed paid for medical care when injured, the physician is left, as is said in the vernacular, "to hold the bag."

Another way in which some of these cases work out is this: A man is injured and the physician is called as before. When the bill is sent to the employer the physician is informed that the employer is insured in the X Y Z accident insurance company, to which the physician is referred. The insurance company asks the physician kindly to fill out numerous blanks giving all the details of the accident, the character and extent of the injuries, the duration of the disability, if any, etc., and

when it has obtained all the free information it desires out of the physician it breaks the news to him that it has already paid hospital bills, etc., to the extent required by law and that it has no further liability in the case. Or if the insurance company cannot hide behind that technicality, it asks the physician for the amount of his bill so as to have it on record, and then informs the physician that the rules of the home office require that all doctors' bills be fully itemized, and that it will be necessary for him to itemize his bill, setting forth the exact charge made for first aid and for every subsequent attention and exactly what was done each time. When this is done the reply comes back that the company allows only so much for first aid, so much for this operation and that, and so much for subsequent care, etc., which fees are about 30 per cent. of what they should be for the work actually done, and the physician may accept that or not as he likes.

NEED OF COOPERATION BY PHYSICIANS TO SECURE JUSTICE

These are merely some of the ways physicians are carrying, without remuneration, a large part of the burden of workmen's compensation acts which should fall on the industries. And they will be obliged to submit to this imposition and to carry this burden, and others which seem imminent in the way of compulsory health insurance acts, unless they wake up and are willing to cooperate to secure common justice.

Medicolegal

Privilege as to Physician Employed Prior to Injury

(*Hirschberg v. Southern Pac. Co. (Calif.)*, 183 Pac. R. 141)

The Supreme Court of California, in affirming a judgment in favor of the plaintiff, in this action to recover damages for personal injuries, holds that, under the statute with regard to privileged communications which was in force when the cause of action arose, the plaintiff did not, by testifying as to her injuries and by permitting a physician who treated her for them to testify regarding them, waive her privilege with reference to a physician who had treated her several years before her injury. The court says that it has been held that if a patient offers the testimony of one of several physicians attending the case at the same time, or who were present at a consultation, the privilege has been waived, so that the testimony of all of them will be received. Likewise, when different physicians have treated the patient at different times for the same injury and the patient calls one of the physicians to testify, it has been held that this constitutes a waiver as to all the physicians. But the court has found no authority supporting the contention in this case that because the plaintiff and her physician testified fully as to her condition after her injury, the ban of privilege was thereby waived as to information acquired by another physician while acting as her physician several years prior to the injury complained of. Nor does the court think that it ought to hold otherwise in this case than as stated, although the tendency of the decisions in recent years has been toward a less liberal application of the ban of privilege, and in California privilege in cases of damages for personal injuries has been abrogated since this cause of action arose (Statutes of 1917, p. 954).

Evidence of Violating Harrison Narcotic Law

(*Thompson v. United States (U. S.)*, 258 Fed. R. 196)

The United States Circuit Court of Appeals, Eighth Circuit, in affirming a judgment of conviction of defendant Thompson of violating the Harrison Narcotic Law, says that a careful reading of the testimony was convincing beyond a doubt that the defendant, under the cloak of a practicing physician, sold narcotics, and not in the regular practice of

his profession for the purpose of curing addicts, and it was the duty of the trial court to submit the issues of fact to the jury, whose finding was conclusive in this court. It was assigned as error that physicians were permitted to testify as experts as to the well-recognized methods among the medical fraternity of treating persons addicted to the use of narcotic drugs for the purpose of curing them of the habit. Such evidence was admissible, but not conclusive. If physicians and the others mentioned in the exceptions of Section 2 can sell and dispense these narcotics, regardless of the fact whether it is done in good faith for the relief of a patient, then the moral object of the act is entirely defeated. It certainly cannot be claimed that a physician selling these narcotics, not in good faith, for the purpose of securing a cure of one suffering from an illness, or to cure him from the morphin habit, is doing so "in the course of his professional practice only," as prescribed by the express language of the act. For the purpose of establishing the intent and bad faith of the defendant, the testimony of other witnesses to having purchased narcotics from him, without his personally attending them, he sending the narcotics to them by express, they living in other states, was admissible. The defendant requested that the jury be instructed that under the act of Congress a physician cannot be convicted for dispensing the prohibited narcotics in the treatment of a patient, whose application is made by letter, and although the physician never comes into personal contact with such patient, provided he reduces the amount on each succeeding shipment of morphin, and furnishes it as in treatment for a morphin habit, in the course of professional practice only. But this requested instruction was in conflict with the act. It lacked two indispensable conditions: first, that the physician furnished the drug in good faith; and, second, that he made and kept the required record.

NEW YORK ACADEMY OF MEDICINE

Stated Meeting, held Feb. 19, 1920

The President, DR. GEORGE DAVID STEWART, in the Chair

The Prevention and Serum Treatment of Lobar Pneumonia

DR. RUSSELL L. CECIL: The old theory was that most persons carry pneumococci in the upper respiratory tract, and that with lowered resistance autogenous infection occurs; more recent studies indicate that the normal mouth rarely harbors a virulent type of pneumococcus except when the person has been exposed to the disease, Types I, II and III being rarely found in healthy persons except among physicians and nurses who have been caring for some one with the disease. In the treatment of pneumonia, the patient should be isolated. Everything that has come in contact with him should be sterilized. Prophylactic vaccination may possibly offer more effective protection against pneumonia than is afforded by sanitary measures. Observations were

made as to the value of prophylactic vaccination against Types I, II and III pneumonia at Camp Upton, where about 40 per cent. of the camp strength of 12,500 men were vaccinated and 60 per cent. remained unvaccinated. Those vaccinated received three injections of a pneumococcus saline vaccine of Types I, II and III, the first dose being 3 billion, the second 6 and the third 9 billion. The plan was to keep the men under observation for five or six months; but they departed at the end of ten weeks, during which time no case of pneumococcus Type I, II and III infection developed among the men who had received the three inoculations of the vaccine. There were only seventeen cases of pneumonia of all types among those receiving the vaccines, while there were 173 cases of pneumonia among the unvaccinated. Among the unvaccinated the mortality was 28 per cent., as against 11 per cent. among the vaccinated.

Further experiments at Camp Wheeler under somewhat different conditions, and with the use of a lipovaccine instead of the saline vaccine used at Camp Upton, indicated that the lipovaccines did not possess so great a degree of antigenic action as the saline vaccine. Here there were under observation about 16,000 men, 80 per cent. of whom were vaccinated against Types I, II and III pneumonia. Among the vaccinated there were thirty-two cases of pneumonia, and among the unvaccinated, forty-two cases. The mortality among the vaccinated was 21.7, and among the unvaccinated, 22.3. In connection with the use of the lipovaccines, it was found that the antibodies did not develop until a week after vaccination. A revision of their figures on this basis showed eight cases of pneumonia of the types vaccinated against.

Dr. Blake and I have conducted animal experiments at the Army Medical School at Washington with a view to confirming these results. The monkey is especially suited to such investigation, as it has pneumonia almost like man. When given large doses of the pneumococcus the monkey always died, and at necropsy the same kind of consolidation of the lung was found as in man. We were able to protect monkeys with vaccine made from living cultures of pneumococci, but with the killed cultures we have not been able to get a satisfactory immunity. When, however, large doses of killed culture were administered in three subcutaneous injections, none of the monkeys thus protected by vaccination got pneumonia, but the controls did. Experiments on Philippine monkeys showed them much more susceptible than the rhesus monkey. Small doses of pneumococcus vaccine given intravenously to rhesus monkeys gave complete protection. These experiments gave a rational basis for human pneumococcus vaccination. The reactions following these injections were about the same as those following antityphoid inoculations, but larger doses were required. There is certainly indication for vaccination against pneumonia in the army, in recruiting stations, during epidemics of influenza, in institutions, and in outdoor workers. It is perhaps also indicated for nurses, physicians and hospital attendants exposed to pneumonia, and in persons subject to repeated attacks of pneumonia. Vaccination against pneumonia is contraindicated in those suffering from pulmonary tuberculosis and in acute respiratory infections. Type I antipneumococcus serum is effective against Type I pneumonia, and by its use in the work at the Rockefeller Institute the mortality of that type of pneumonia has been reduced from 30 to about 7 per cent. All the monkeys treated with Type I serum recovered, though they had been infected with lethal doses of Type I culture. The controls died. If serum was given early, the disease was practically aborted.

DISCUSSION

DR. FRANCIS G. BLAKE: This study of prophylactic vaccination in influenza and pneumonia offers great hope of supplying us with the means of preventing pneumonia, at least to a certain extent. These experiments have brought out three points very definitely: 1. The importance of beginning treatment early, a point which cannot be too strongly emphasized. The serum treatment should not be regarded as a last minute effort to rescue the patient from the grave, and that is the general rule in any disease treated by serum. 2. There should also be a great deal of enthusiasm in maintaining persistent treatment at least three times a day and

not desisting until the patient is well. 3. Even though, through unavoidable circumstances, treatment cannot be begun early, it should always be tried in the hope that severe cases may be saved as in the monkeys.

DR. HENRY T. CHICKERING: In the clinical study of pneumonia, Dochez and others have found that immune bodies and agglutinins last for only a short period; but these may not be the only index of immunity. It is important to emphasize the advantage of early use of the serum. If one is able to type the case within forty-eight hours of the chill and there are signs of incomplete consolidation, one or two treatments with the serum may be sufficient, whereas later on eight or ten treatments will be required. The time to get the sputum is at the first examination when, in attempts at deep breathing during percussion, coughing and expectoration are usually started. Treatment should be continued as long as the temperature is above 101 F. and one is certain it is not due to complications. There is an impression that empyema occurs more frequently in pneumonia cases treated with serum than in those not receiving this treatment, and it has been observed that empyema is rather infrequent in Type III pneumonia. The reason is that, in the severe cases of Type III pneumonias, death usually supervenes before the empyema stage is reached. When serum is used, more of the cases are saved and reach the empyema stage. In working with mice, it has been observed that there are certain maximum doses of pneumococci above which the serum exerts no effect. The same thing is probably shown in patients seen late when seventy-five or a hundred colonies of the pneumococci are found in the field, and in whom serum, even if given persistently, has no apparent effect, the patient dying either of pneumonia or of some complication.

DR. RUSSELL L. CECIL: My impression is that pneumococcus immunity lasts several months, and that it will be necessary to repeat vaccination every year in order to give protection during the season when pneumonia is prevalent. This is a subject we expect to investigate in the near future. There seems to be no relation between the degree of immunity and the amount of protective substance in the serum of the monkeys. An argument against the influenza bacillus as a cause of influenza is that it is difficult to obtain this organism by culture. We have found that with monkeys the influenza bacillus in some instances appeared and then suddenly disappeared, and that it spread rapidly from one part of the respiratory tract to another.

Relation of the Influenza Bacillus to Influenza

DR. FRANCIS G. BLAKE: None of the objections usually raised can be maintained as valid reasons for abandoning the conception of the possible etiologic importance of the Pfeiffer bacillus in relation to influenza, since it is well known that many bacteria whose etiologic relationships to various diseases affecting the respiratory tract is fully established may be found in the upper respiratory tract of healthy persons, and are often found in association with other pathologic conditions than those which they commonly cause. It has been thoroughly established that *B. influenzae*, at least certain strains of the organism, may be pathogenic for man, since it has been found as the only organism present in cases of meningitis, endocarditis, pneumonia and other conditions. That during the epidemic many laboratory examinations failed to show the presence of this organism is probably due to the fact that such examinations were carried out under the stress of war conditions, frequently without the use of adequate mediums or sufficient attention to the cultural peculiarities of the influenza bacillus. The failure to reproduce the disease in animals may be explained by the fact that in the majority of animal experiments reported in the literature, the methods of inoculation have been subcutaneous, intraperitoneal or intravenous, and it is not to be expected that a disease that may safely be classified as a respiratory infection could readily be reproduced in animals by the introduction of the virus by other than the natural mode of infection. That attempts to reproduce the disease by inoculation of the mucous membranes of the respiratory tract have been unsuccessful may be due to failure to take into consideration that such pathogenicity as the influenza bacillus

possesses may be rapidly lost on artificial cultivation outside the animal body. Our experiments show that *B. influenzae*, when attention is paid to maintaining it at a proper grade of virulence, can initiate in healthy animals an infection of the mucous membranes of the upper respiratory tract which may spread by continuity to the lower respiratory tract, producing a tracheobronchitis and, in a certain proportion of the cases, a characteristic type of bronchopneumonia. Control experiments with highly virulent strains of pneumococci and hemolytic streptococci have shown that these organisms do not possess this property, and that they must gain admission to the bronchi before they can initiate an infection of the respiratory tract. The disease experimentally produced by inoculation of the nasal and buccal mucous membranes with *B. influenzae* was essentially identical with influenza in man with respect to its symptoms, clinical course and complications. *B. influenzae* can produce in animals a characteristic type of bronchopneumonia which is identical with the kind of pneumonia that has been described as typical influenzal bronchopneumonia of man and has been ascribed to infection of the lungs with *B. influenzae*. In short, *B. influenzae* can produce in animals the clinical syndrome of influenza. As harmonizing apparently opposing facts, I would suggest that the pandemic disease was primarily initiated by a yet undiscovered organism, and that there resulted under the influence of this virus a concomitant infection with *B. influenzae* which was responsible for the principal clinical manifestations of the disease influenza. Only future investigation can determine whether this assumption is correct.

DISCUSSION

DR. WILLIAM H. PARK: Four of our laboratory assistants at different times have been sprayed with fresh cultures of influenza bacilli accidentally. Two of these persons developed a moderate infection, and in both of these the type of culture which was sprayed into the nostrils was the type obtained during the infection and for many days afterward. The other two did not develop the infection, although one became a carrier for several weeks. Dr. Blake spoke of the fact that the early fulminating cases might show during the first day the Pfeiffer bacillus in pure culture or nearly pure culture, and later would show mainly the streptococcus, pneumococcus or other organisms. We have not found this always to be the case. Only a minority of our acute cases (20 per cent.) at death showed only influenza bacilli in the lungs. Dr. Williams and her associates have tried to find a filtrable virus, but with negative results. Inoculations in students of filtrates from nasal washings had also not produced infection. The simple finding of a filtrable virus in a few cases would, of course, prove nothing more as to the etiology of influenza than finding an unidentified new pathogenic microbe. It would still be necessary to prove that such a virus was the cause of the pandemic and not one of the complicating infections. One of the questions that must be considered in etiologic investigations is: "What are the marks of a case of epidemic influenza?" Dr. Williams has searched the cultures from over 100 cases but has not found the epidemic strain. When investigators have spoken of the significance of the Pfeiffer bacillus in 100 per cent. of the cases, they used the name in a very liberal way; they really meant that they had found very different types of the organism. These could not be from the same epidemic source. These findings supported strongly the belief that these persons were influenza bacillus carriers before they were attacked by influenza. Earlier investigations have always indicated this. The Pfeiffer bacillus has been found in virtually every case of whooping cough, in 90 per cent. of measles cases, and also in a large percentage of cases in other respiratory infections. In her search for the epidemic strain, Dr. Williams has taken cultures from separate groups and has isolated ten or twenty colonies from the cultures of each. In order not to miss the infecting strain, she selected those developing first on the plates, those developing later, and those developing last. She has picked out these colonies from the cultures from undoubted epidemic influenza; but instead of finding an epidemic strain, she found a multitude of types. These findings have convinced us that the Pfeiffer

bacillus has not been established as the cause of influenza, and have led us to believe that it was some other micro-organism. These experiments of Drs. Cecil and Blake have to my mind been very important in designating that lesions can be formed in monkeys by the Pfeiffer bacillus similar to those seen in the pneumonias occurring in influenzas.

DR. HANS ZINSSER: Drs. Cecil and Blake have, indeed, carried out Koch's postulate with the influenza bacillus and have produced lesions similar to those produced by this organism in some human cases, but the question as to whether the condition they have produced is true epidemic influenza or corresponds merely to a secondary condition analogous to pneumococcus and streptococcus lesions is still open. The conditions that Dr. Cecil and Dr. Blake produced in the monkeys' lungs, and the similar condition often spoken of as influenza at the present time, are not those seen in the cases of influenza during its early epidemic stages in France, and as I understand in this country as well, a condition characterized by rapid dissemination, sudden onset, violent headache, muscular pain and fever, but absence of respiratory or other local symptoms. It usually lasted three days, and all the patients recovered. Later, throat symptoms appeared; and in these, influenza bacilli were found. This was certainly not the disease that was seen later in the camps in this country and is being seen in the hospitals, associated with the pneumococcus or the hemolytic or other streptococcus. It is difficult to understand why a patient should be so terribly ill with nothing but a small focus of influenza bacilli in the throat; this can be explained only on the basis of the production of a poison by the organisms comparable to exotoxins of other bacteria. Recent work in the Columbia Medical School laboratory by Mrs. Parker shows that the influenza bacilli produce powerful poisons in the early stage of their growth in liquid mediums, which are toxic for rabbits. Just what these poisons are is not yet clear to us; but it is not impossible that they may actually be formed in the body, and would account for severe symptoms accompanying the localized infections. At Dr. Longcope's clinic we are beginning to examine convalescent patients by complement fixation with influenza bacilli. A great many of them seem to have shown complement fixation with various antigens, but the work is just beginning and it is very difficult to obtain serums from any one at present and be sure that they are normal. The work of Drs. Cecil and Blake has made it seem somewhat more likely that the influenza bacillus is responsible for what is commonly spoken of as influenza, but it does not bring positive proof of this particular phase of the problem; and while I am inclined to favor the etiologic significance of the influenza bacillus, final judgment must be withheld until some of the apparently contradictory points of evidence have been more thoroughly cleared up.

DR. FRANCIS G. BLAKE: The point to be emphasized is that although we can produce pneumonia by the influenza bacillus, this bacillus was able to initiate an infection of the upper respiratory tract which seemed the same as the type that appeared in the spring of 1918. I saw a great deal of that type at Fort Sam Houston, and believe it was the same as the type they were having in France. Is it not possible that a number of strains of the influenza bacillus were responsible for the epidemic? In an epidemic of pneumonia among monkeys, at least four types of the pneumococcus were concerned.

Treatment of Influenza

DR. SAMUEL A. BROWN: In the treatment of influenza, toxicity is the factor to be kept in mind from the beginning of the disease to the very end. Treatment must be directed first toward the destruction of the invading organism locally and generally. All cases, though very mild, should be regarded seriously. The treatment should consist of rest in bed, a cathartic, and local treatment of the nasal and respiratory mucous membranes with alkaline irrigations and a solution of argyrol or other preparation of silver. Of the drugs of value in the constitutional treatment, the preparations of quinin stand out as fundamentally the nearest to a specific which we have, though we are entirely unable to prove its destructive power on the specific bacteria. Quinin should be

given in 2 or 3 grain doses every two or three hours until there is evidence of cinchonism. In addition, phenacetin for the control of pain, headache and temperature, small doses of codein for control of the cough and salicylates as analgesics may be given as required. Another plan of treatment in which there is dryness of the skin, cough and restlessness consists in the administration of Dover's powder, 3 grains, and 3 grains of quinin every three or four hours. The former plan seems preferable. It is important to increase elimination by the ingestion of alkaline waters and by means of high colonic irrigations. The depression associated with the end of the active stage should be counteracted in the beginning by moderate alcoholic stimulation and forced feeding. The treatment during the convalescent stage is most important and often neglected. Associated with the use of quinin, camphor may be used hypodermically. During convalescence the hypodermic administration of strychnin or arsenic on alternate days should be prescribed, together with absolute rest and stimulating massage. In recent prescribing many have omitted to use some of the old-fashioned preparations which have been useful for generations and which are just as useful today if selectively applied.

DISCUSSION

DR. HUBERT V. GUILÉ: Influenza is of such short duration, and the outcome is so invariably favorable, that it is difficult to say just how much the results are due to treatment and how much to the patient's own immunity. One is almost justified in regarding any case of influenza that has persisted more than five days as more than likely to have developed pneumonia. Here, again, with the exception of pneumonia of Type I, the treatment is purely symptomatic. At present I fear the great bulk of treatment in pneumonia is directed to the prevention of circulatory and heart failure when it is by no means certain that this is a frequent cause of death. Haldane has recently brought to notice the importance of the administration of oxygen inhalations in the treatment of anozemia, which he defines as a condition in which the rate of supply of oxygen to the tissues by the blood in the systemic capillaries is insufficient for the normal processes of life. This he maintains is a common situation in the bronchopneumonias of the so-called influenzal type. Another procedure that has proved useful, the result of our experience abroad, is the use of intravenous hypertonic glucose solution. This seemed to be of distinct value in the critically ill presenting marked toxic symptoms, its beneficial effects being attributed to the restoration of dehydrated tissues, to its slight caloric value, and to its possible tonic effect on the heart muscle. Nonspecific protein therapy has been applied in bronchopneumonia, and seems to promise some assistance along these lines. The same statement holds true of passive immunity obtained by the use of the serum of convalescent patients. Lumbar puncture is occasionally of value in delirious patients, and is of value in ruling out the possibility of meningeal involvement. For emergency stimulation in pneumonia, camphor and caffeine in my experience are most efficient, with epinephrin if the blood pressure is unduly low. Pituitary extract has been useful in combating tympanites. The patient should, of course, be digitalized early in the course of the disease.

Obstetric Teaching Hospitals in London.—By all means let the small number of hospitals which can do so enlarge their existing accommodation for maternity cases and at the same time take steps to improve their teaching, which at present is admittedly defective; but the total number of beds which these hospitals will be able to set aside for midwifery will be quite inadequate to fill the demand. It would be suicidal for all the medical schools of London to try to establish maternity wards with a sufficient number of beds; this should be attempted by not more than three or four schools and the students of the other schools should obtain their clinical instruction either at one of the schools furnished with a maternity ward, or, better, at one of the new and large midwifery institutions, of which at least half a dozen will be required in the different areas of London.—*Lancet*, Dec. 13, 1919.

January, 1920, 3, No. 11

- *Occult Tuberculosis. H. Sewall, Denver.—p. 665.
- *Serologic Studies on Tuberculosis. Complement Fixation. S. A. Petroff, Trudeau, N. Y.—p. 683.
- *Early Roentgen-Ray Diagnosis of Ulcerative Tuberculous Colitis. L. Brown and H. L. Sampson, Trudeau, N. Y.—p. 698.

Occult Tuberculosis.—A large group of patients suffer symptoms from a tuberculous infection which is nonprogressive. The symptoms are caused by a subtle intoxication which undermines the functional powers and coordination of all vital tissues. This condition Sewall terms "occult tuberculosis." The patients, as a rule, are not definitely sick. There is a general functional insufficiency with lack of staying power that is brought out by slight physical strain. Neuralgic pains, headache, dizziness, undue fatigue and nervousness are common symptoms. In women, menstruation is apt to be scanty, or is frequently missed. The temperature is usually not elevated but may rise slightly after exercise. The lungs are rarely suspected, but they give auscultatory and roentgen-ray evidences of slight sclerosis involving, especially, the hilum lymph nodes and the upper bronchial radiations. The symptoms may often be traced to circulatory or hormonal insufficiency. Many of these patients, Sewall says, have probably been classified under the title of "effort syndrome" or "neurocirculatory asthenia." The most valuable objective sign of occult tuberculosis is the reaction of the blood pressure to slight strain, such as changing from the supine to the erect position. Most of these patients have vascular hypotension but the most significant feature is an abnormal lowering of pulse pressure and its tendency to progressive subsidence when the erect posture is assumed. This may be due to inordinate fall of systolic pressure or to rise of diastolic pressure in the upright as compared with the recumbent position. This pressure change is not specific of occult tuberculosis, but after exclusion of focal infection, it should suggest this condition and lead to the application of diagnostic methods.

Complement Fixation in Tuberculosis.—Petroff reviews a number of antigens that have been employed and discusses their nature and chemical composition. He has isolated substances corresponding to lecithin, cephalin, sphingomyelin, carnithin and cuorin from tubercle bacilli, and compared their antigenic properties with those of various tuberculo-proteins. Lipins are anticomplementary in large doses, and have no antigenic properties in small doses. Proteins do not give as strong reactions as proteins combined with lipins. The primary incubation time is very important and from one and one-half to two hours is best. Complement fixing antibodies are probably globulins or substances absorbed with the globulins. To get satisfactory results, it is important to have a proper hydrogen ion concentration of the salt solution, to have the glassware thoroughly cleaned and to incubate at a temperature of between 35 and 40 C. Petroff claims that the test in tuberculosis is more specific than the Wassermann test in syphilis.

Roentgen-Ray Diagnosis of Tuberculous Colitis.—According to Brown and Sampson, the clinical picture in the early latent stages of tuberculous colitis contributes little to diagnosis. However, certain roentgen-ray shadows seen from six to twenty-four hours after a barium meal show definitely the presence of colonic ulceration, although their absence does not exclude it. They also show hypermotility and spasm of filling defects, and such a picture in a patient with pulmonary tuberculosis should lead to a definite diagnosis of colonic tuberculosis. The condition is far more frequent than has been hitherto taught, and must be excluded in all advanced as well as early cases with abdominal symptoms, before submitting them to radical treatment. No examination of a patient with pulmonary tuberculosis can be considered complete without a roentgen-ray study of the intestines.

- *Placental Tumor. R. D. Margeson, Boston.—p. 200.
- *Rupture of Pectoralis Minor Muscle. W. P. Coues, Boston.—p. 200.

Placental Tumor.—Margeson reports what he believes to have been an angioma of the placenta. The tumor measured 10 by 6 by 3 cm. and was completely surrounded by amniotic membrane, being attached to the placenta by a structure similar to the umbilical cord, containing vessels, and measuring 6 cm., thus differing from a succinuriata by having no uterine attachment. The specimen was destroyed by mistake before a microscopic examination could be made.

Rupture of Pectoralis Minor Muscle.—While lifting on a tackle and falls with the left arm high in the air, Coues' patient gave a quick jerk on the rope and felt a sudden severe pain above the nipple of the left breast. The load was between 800 and 900 pounds. The patient complained of pain about the left breast on attempting to use his arm since that time, eight months ago. The region of the left breast was distinctly more prominent than the right. There was a diffuse globular swelling under the breast, extending from the anterior border of the axilla to just above the nipple line. The mass was soft, doughlike and somewhat tender to direct pressure. It was most marked near the axillary line. Its general shape was somewhat that of a cucumber. Elevation of the shoulder was possible but painful. Adduction of the arm caused distinct pain in the pectoral region. The grip of both hands was equal and strong. There was no disturbance of sensation of hand, forearm or shoulder. There was no atrophy. The greater pectoral muscle was very well developed, and seemed to be functioning perfectly well. The nature of the injury and appearance of the soft tumor mass in the direct position of the lesser pectoral muscle, would seem to make the diagnosis of this unusual injury fairly certain.

- *Refinement of Colorimetric Methods; Indigocarmine as Functional Test. G. G. Reinle and E. S. DePuy, San Francisco.—p. 49.

Pneumoperitoneum.—According to Alvarez, the first one to show roentgenograms taken after injecting air into the abdomen of a patient who had been tapped for ascites was Lorey in 1912. Weber began to work out this technic on animals and cadavers in 1912. The harmlessness of this procedure in suitable cases seems to have been well established, as no accidents have been reported from the clinics in which it has been used extensively. Rabbits and guinea-pigs can be distended with oxygen or carbon dioxide to a degree not approachable in man, without producing any signs of distress or concern. The rapid absorption of these large quantities of gas does not bother their respiratory centers. Alvarez is convinced that this is the biggest advance in roentgenologic technic since the introduction of the bismuth meal by Cannon in 1898.

Indigocarmine as a Functional Test.—Two standards are used by Reinle and DePuy in each determination: (1) a standard aqueous phenolsulphonephthalein, 0.006 to 1.000; (2) a standard dark amber urine phenolsulphonephthalein, 0.006 to 1.000. By a dilution of the urine standard with the water standard, a separate standard was established in each case, and that standard was compared with the urine under investigation. In one of the parallel tubes to the colorimeter the patient's urine, diluted to some multiple of 1,000, is brought up to the 10 c.c. mark. In the opposite tube is

placed 4 or 5 c.c. of either of the standards. A glance shows whether there is too much or too little yellow coloring matter, and either the aqueous standard or the urine standard is added until an exact match is obtained. The whole process is said to occupy probably five minutes, and is so easily accomplished that the test can be performed by any trained attendant. Having solved the problem of actually matching colors, which the authors are able to do within 0.5 per cent., they then check their findings with reflected light against the findings of transmitted light. The authors use indigocarmin instead of phenolsulphonephthalein. The amplified indigocarmin test is not offered as in any wise a substitute for the phenolsulphonephthalein test, except under conditions where the latter cannot be used, but it is proposed as either an alternative test or as a supplementary test when urine is uncontaminated by blood.

Dilatation of Lateral Ventricle as Common Brain Lesion in Epilepsy. D. A. Thom, Palmer, Mass.—p. 41.

Dilatation of Lateral Ventricle in Epilepsy.—The brains of seventy-five epileptics were examined postmortem by Thom. Fifty-seven of these specimens presented gross brain lesions; thirty-one presented cortical lesions as well as dilated ventricles; sixteen presented lesions of the cortex alone, while fourteen, with normal appearing cortex, presented dilated lateral ventricles. Of the whole number of forty-three brains presenting cortical lesions, the hind portion of the brain was by far the most frequently affected, especially the occipital lobes. The convolutional shrinkage in this region was often marked on the brains so that the condition was acquired rather than of congenital origin. Next in order of frequency was the general cerebral gliosis, where the entire cerebellum appeared to be involved. Softenings were noted only six times, once being general and five times focalized. In only two cases of the seventy-five was there evidence of arterial rupture. Gliosis and atrophy of one hemisphere alone was noted in eight cases of the forty-one with dilated ventricle; twenty-seven brains presented abnormalities of the cortex; in fourteen instances the cortex was not grossly abnormal but the ventricular dilatation was of such a degree as to

leave no doubt of its abnormality, thus raising the question whether the lesions affecting primarily the white matter can be a factor in the production of epilepsy.

Cocain Intoxication in Rabbit. C. A. Mills, Cincinnati.—p. 355.

Active Principles of Pituitary Gland.—A method of preparing crystalline residues, very active physiologically, from extracts of the posterior lobe of the pituitary gland is described by Dudley. It consists in extraction of the dried and powdered infundibulum with acidulated water, treatment of the solution with colloidal ferric hydroxide and subsequent continuous extraction of the filtrate with butyl alcohol at reduced pressure. This extract yields a crystalline residue which contains all the uterine stimulant, together with some of the pressor principle and contaminating substances. Dudley claims the uterine stimulant and histamin are not identical, as suggested by Abel and Kubota, but are two distinct chemical substances. The only point of similarity observed is that both are readily extracted from alkaline solution by butyl alcohol. The pituitary uterine stimulant is more readily extracted from acid solution than the pressor principle.

Perfusion of Medulla of Turtle.—The experiments reported by Bush seem to indicate that on the isolated medulla of the striped turtle, atropin, 0.02 per cent., and caffeine, 0.04 per cent., exert little or no registrable influence; whereas strychnin, 0.0033 per cent. produces a prompt, though temporary, stimulation of the cardio-inhibitory center.

Comparative Toxicity of Local Anesthetics and of Antipyretics for Earthworms.—The investigation made by Sollmann furnishes data of the toxic concentrations of local anesthetics and of antipyretics for earthworms. These are not paralleled to the toxicity for mammals, since the mechanism of the fatal effects is different.

Anthelmintic Action of Benzyl Alcohol and Benzyl Esters.—Experiments were made by Macht on both earthworms and roundworms of the pig with benzyl alcohol, benzaldehyd, benzyl acetate and benzyl benzoate. It was found that all of these drugs exerted a toxic effect on the worms but not in the same degree. The least effective was benzyl benzoate. Its weak action, however, must be for the most part due to its poor solubility and penetrating power. Benzyl alcohol was found to be the most powerful anthelmintic of the drugs studied. A 0.5 per cent. solution of it, and even weaker solutions, killed earthworms rapidly. Benzaldehyd came next in its efficiency and benzyl acetate was third.

Action of Curara on Output of Epinephrin from Suprarenals.—Stewart and Rogoff found the curara in doses sufficient to paralyze the skeletal muscles in the cat markedly depresses the output of epinephrin from the suprarenals. The depression begins promptly and may be still well marked when paralysis of the muscles has begun to wear off. While no attempt was made to compare exactly the doses required to paralyze the epinephrin secretory fibers and the cardio-inhibitory fibers, a marked diminution in the epinephrin output was observed in samples of blood collected from the suprarenals at a time when stimulation of the vagus caused inhibition of the heart.

*New Method of Treating Remote Manifestations of Gonorrheal Infections. M. Stern and I. S. Ridler, New York.—p. 190.

Unusual Symptoms and Signs Observed in Last Influenza Epidemic.—The cases cited by Greenberg were: influenza with intestinal hemorrhages; influenza with onset of hematemesis; influenza followed by acidosis and toxic vomiting; influenza with acute nephritis and suppression of urine in a patient suffering from pulmonary stenosis and paroxysmal tachycardia (auricular fibrillation).

New Method of Treating Remote Manifestations of Gonorrheal Infections.—For nearly one year, Stern has been treating all cases of arthritis with intravenous injections of 20 c.c. of a solution of sodium iodid, 2 gm. in 20 c.c. of water. This treatment was repeated every four days. After having treated ten arthritis patients with extraordinary results, intravenous injection of sodium iodid was resorted to in cases of acute orchitis, with rapid subsidence of the acute symptoms. Prostatic infections also behaved in a manner quite different from that which Stern had been accustomed to seeing. By thus extending the field of application of this treatment he now has records of 100 patients discharged germ free and apparently cured, though no follow-up system was possible.

Case of Congenital Total Hemihypertrophy.—Coston's patient was 22 months old, the fourth child of healthy parents of rather low mentality. The other three children were normal and healthy, and mentally above their parents. This one had never been sick, and seemingly was of good mentality. The mother was well during the pregnancy. There is no history of defective development in any member of the family, except a second cousin of this child's on the mother's side, who has six toes on his right foot. This child was born after a very quick and easy labor. It was observed immediately on his birth that one side was much larger than the other. This involved the whole left side from the crown of the head to the soles of the feet.

Special Medical Board, Corresponding to Patent Office.—Soresi's idea is that the function of this medical board should be to establish and protect the priority of ideas relating to medical subjects.

Milk Produced in Southern China.—Three classes of milk animals were studied by Levine: European cattle, the native water buffalo (known in the Philippine Islands as carabao) and the native humped cattle. The work has been done chiefly in the vicinities of Canton and Hongkong, the only regions in Kwangtung (which is the southernmost province in China) where dairying has yet developed into an industry of any extent. The milk of the Canton buffalo contains nearly four times as much fat as the European cow, twice as much protein, but only two thirds as much sugar. The ash content is about the same; the water content is slightly less. The food value of the milk of the water buffalo was discussed fully in an article by Cadbury, published in the *American Journal of Diseases of Children*, January, 1920, and abstracted in THE JOURNAL, Jan. 17, 1920, p. 202.

Subacute Combined Degeneration of Spinal Cord.—Under this heading Somerville cites a case of anemia and a combined degeneration of the posterior and lateral columns of the cord, running a fairly acute or subacute course. The patient was a woman, aged 55 years. Her trouble began insidiously fifteen months previously, with numbness and tingling in the feet and legs, which has gradually extended up above the umbilicus. Recently, there developed numbness and tingling of the hands and wrists, weakness of the lower extremities and a rather marked ataxia; some difficulty in voiding urine, but no retention nor incontinence. She complained of a sensation in the lower extremities as if they were tightly bound with bandages. She had had intestinal attacks with some rise of temperature at intervals of every few weeks. Her color was pale and sallow; heart and lungs were negative. Hemoglobin was 63 per cent.; red blood corpuscles numbered 2,300,000, with slight variation in size, but no nucleated cells. In every stool examined there was found the *Cercomonas intestinalis*. Somerville calls attention to the very great importance of examination of the intestinal discharges of these patients, because of the possibility that the symptoms are produced by an intestinal parasite.

Spinal Muscular Atrophy Probably of Werdnig-Hoffman Type.—Knox and Powers report three cases occurring in one family, one boy and two girls, aged 14 months, 6 weeks and 3 months, respectively. The authors incline to the belief that the symptoms in these three cases, namely general symmetrical muscular weakness, noted at birth, with loss of reflexes and diminution in response to electrical stimulation, can be explained most satisfactorily on the assumption of a primary spinal atrophy and secondary muscular involvement, although the possibility of a reverse process cannot be excluded. The third patient, who is still living, has apparently improved somewhat, which is accounted for by the development of certain intact and enervated muscle fibers.

It would seem to the authors, from a consideration of the growing literature, that many transitional cases do occur between the group of cases described as amyotonia congenita (Oppenheim) and those of infantile spinal muscular atrophy (Werdnig-Hoffman); that both these conditions may be due to a congenital defect in development of the lower motor neuron tract, affecting both certain ganglion cells of the cord and the muscles they supply. In general, it is true that the cases of amyotonia congenita represent the less intense and progressive involvement.

Infectious Meteorism.—In the two cases cited by Einhorn a laparotomy was performed. There existed no mechanical obstruction along the digestive tract. The small intestine in parts and the entire colon were filled with gas, and the peritoneal covering of these organs looked glittering and reddish, showing the presence of peritonitis. Both patients died soon after the operation. The disease, appearing in both patients in an acute form with the accompaniment of fever, suggested an infection (probably bacterial) as its cause. Einhorn also cites one case in which this condition followed an attack of influenza. Treatment should be directed toward combating the infection and relieving the bowel difficulty. Absolute rest, flushing of the system with water, and relieving the digestive tract of accumulated gas and stagnant contents are the main aims to be accomplished.

Uncinariasis and Manifest Tuberculosis.—In forty-six cases of suspected tuberculosis, Adams failed to find any evidence justifying the diagnosis of tuberculosis but established the presence of existing infection with hookworm in thirty-two cases, and developed clear histories of previous infections of considerable severity in the remaining fourteen cases. The provisional diagnosis had been made in each instance chiefly because of the presence of adventitious sounds over the upper chest. Investigation disclosed the entire absence of râles and demonstrated the presence of joint sounds ranging from coarse grating to fine crepitations, the latter distinguished only with difficulty from true râles. The majority of these sounds are to be heard over the sternocostal articulations and are transmitted out to the ribs, especially in the vicinity of the clavicle. A comparative study, on one hand, of 100 individuals with clinical evidence of uncinariasis, and of 100 normal subjects, on the other, showed a preponderance of confusing crepitations of about three to one in favor of the former. In old cases of hookworm infection the adventitious joint sounds are not confined to the shoulder girdle and adjacent parts, but are to be heard over several or many of the articulations. In Adams' opinion there is no evidence establishing any specific relationship between the two diseases, and, he says, inasmuch as it has been demonstrated that the mortality from tuberculosis may be reduced by a measure so simple as elimination of hookworm where double infection exists, the obligation of the physician with regard to diagnosis and treatment is apparent.

New Uses of Scrotum.—Two cases are reported by Johnson in which an excess of scrotum was used to advantage in relieving two conditions which have not yielded always to the usual treatments. The first case was one of intractable pruritus ani, in which the skin of the involved area had to be removed. A pendulous scrotum was used to supply the defect. The second case was one of lymphedema of the leg following an operation for right inguinal adenitis. During the operation, which had been performed about six months before, the saphenous vein was injured and the hemorrhage was controlled by sutures en masse. There was an obstruction of the lymph return through the right inguinal lymphatics. The leg did not recede to normal when elevated. The scrotum was not edematous. As the return lymph could not go through the right groin, the problem was to find another course. Finding an unusually long scrotum, Johnson decided to use the entire left side of the scrotum with its subcutaneous tissues and lymphatic channels as a tissue flap below the obstructed area, with the idea of carrying the lymph, which normally returns through the right groin, through the left groin. At the end of two months the edema was entirely relieved.

Diminution of Diaphragm Movement in Tuberculosis of Lungs.—Air entry into the lung is dependent on diaphragmatic and costal movements, hence any diminution in these movements will give rise on the fluorescent screen to diminution of the difference in illumination between inspiration and expiration, and on percussion to the difference in the notes obtained during these two phases of respiration. Berry claims to have seen this many times. Therefore, he regards the use of the roentgen ray as of value in the early diagnosis of pulmonary tuberculosis because this functional derangement of the diaphragm may be seen before there is any evidence of organic change. The same observation has also been made by others.

British Medical Journal, London

Jan. 31, 1920, 1, No. 3083

House Fly as Carrier of *Endameba Dysenteriae*.—It appears from Buxton's research that in a well sanitated area in lower Mesopotamia more than 60 per cent. of all the flies carry human feces; more than 4 per cent. of them carry actual human entozoa and probably at least 0.5 per cent. the cyst of *Endameba dysenteriae*. He believes it justifiable to regard the fly in that country as not only a potential, but an actual and major factor in the carriage of the bowel disorders which are there so numerous. In fact, the egg of any human intestinal worm, or the cyst of any protozoan may be found in the fly if only one looks long enough.

Analysis of One Hundred Consecutive Cases of Cardiac Disease.—Of the 100 patients cared for by Jones, seventy-three complained of pain over the heart or neighboring part of the chest; nine complained of pain in the region of the lower ribs on the left side; in many of the cases the pain was only a dull ache; in all the pain was intermittent. Of these seventy-three patients, thirty-three experienced an increase in the area of the pain; thirty referred the pain to the left arm, two to both arms, and one to the right arm only. Fifty-one patients attributed the pain to exertion. Thirty-six persons stated that mental excitement caused the pain. Thirty-four persons attributed attacks of pain to digestive disturbances. Twenty-one patients complained of pain in bed. Eighty-nine patients complained of shortness of breath after slight exertion. Exhaustion after exertion occurred in eighty-five cases. Palpitation was noticed by thirty-six persons. Faintness was noted in six cases. Giddiness occurred in twenty-nine cases. The rate of the pulse was 76 or under in seventy-one cases; it was above that rate in twenty-nine cases. In two of the latter it was markedly irregular owing to auricular fibrillation. Thirty-six persons had high blood pressure; of these, twenty-five had symptoms of anginal pain. In sixty-one cases the heart was dilated, and in twenty-two of these a murmur was present. Albumin was present in the urine in three cases and sugar in one case.

Direct Cultivation of Tubercle Bacilli from Tissues.—The method of isolating tubercle bacilli from tuberculous tissues devised by Wilson depends on the use of (a) special medium for culture, and (b) the trituration of the tissue with dry quartz sand before the application of antiformin to destroy contaminating organisms. The tissue is cut up into small pieces and is thoroughly rubbed up in a mortar with a small amount of dry sterile quartz sand. The fibrous tissue is disintegrated as far as possible, and the material forms a slightly moist, crumbling mass. The contents of the mortar are then washed into a wide test tube with from 15 to 20 c.c. of sterile saline solution. The sand is allowed to sediment for a few minutes; as it falls, it carries down with it any coarser particles of tissue which remain. The supernatant fine suspension is then pipetted off, and thoroughly mixed with an equal volume of 15 per cent. antiformin. After five minutes, during which it should be stirred continuously, the mixture is centrifugalized at high speed for a few minutes, and the supernatant fluid is discarded. The sediment is shaken up with sterile saline solution and centrifugalized three times so that no trace of antiformin remains. The sediment resulting from the final centrifugalizing is used for making cultures, or, after emulsifying with a convenient amount of sterile saline solution, it is injected into a suitable animal. The medium used is a modification of Dorset's medium in which the contents of eggs are mixed with a three weeks' tryptic digest of horse heart instead of with water.

Pneumokoniosis in Man and Horse. R. P. White.—p. 500.

Control of Infectious Diseases in Industrial Communities. H. Zinsser, New York.—p. 501.

Unreported Cause of Occupational Dermatitis.—Attention is directed by White to a skin complaint which attacks certain employees engaged in the fellmongers yard. From four to twelve small ulcers, the size of a split pea, will be seen on the sides of the knuckles and on the interdigital skin of the fingers. The pullers scrape off the hair or wool by rubbing down the woolly skin with the balls of the naked thumbs and the ulnar edges of the palms of both hands. The characteristic rash and holes appear on these parts in the pullers. If neglected, the ulcers penetrate deeply, the sores easily becoming infected, causing inability to work. An effective trade-shop remedy is a drop of Stockholm tar applied to each hole. This appears to act as a protective, enabling the men to "carry on." Frequent washings of the hands in a weak solution of vinegar and water, followed by the thorough rubbing in of an ointment are helpful preventives. The ointment White prefers is as follows:

	Gm. or Cc.	
R. Zinci oxidi	30	℥ j
Acidi oleici	270	℥ ix
Emplastri plumbi	300	℥ x
Parenol (petrolatum 65; wool fat, 15; warm water to make 100 parts)	1140	℥ xxxviii
Hydrargyri ammoniati	180	℥ vj
Misce. Fiat unguentum.

Case of Mediastinal Tumor Associated with Acute Leukemia. C. R. Harrison and D. McKelvey.—p. 252.

Indications for Cesarean Section.—During the past twelve months Whitehouse performed cesarean section eleven times. The indications were as follows: pelvic contraction, flat pelvis, two cases; pelvic contraction, round pelvis, five cases; placenta praevia (central), one case; eclampsia, three cases. The maternal mortality was nil, and only one baby was lost. This baby died on the fifth day, and its death was caused by neglect on the part of the nurse. Four cesarean sections were performed in the patients' own houses, as emergencies, without any preparation, such as is the usual routine before a prearranged abdominal section. There was no mortality and no morbidity, which, Whitehouse says, goes to prove that the operation may be performed with safety, provided that adequate surgical principles are observed at the time. There were two cases of maternal morbidity, both in nursing homes. One was a case of eclampsia in which the patient's doctor had ruptured the membranes before admission. The other was a case of flat pelvis, where intra-uterine sepsis occurred on the eighth day, in spite of the fact that no vaginal examination had been made prior to operation and the membranes were intact. In this instance the infection was traced to a nurse with a septic finger who was attending the patient. Both patients, however, recovered, and the morbidity cannot be attributed to the choice of the method of operation.

Edema as Symptom in So-Called Food Deficiency Diseases.—His observations led Bigland to the belief that epidemic dropsy is a condition due to affection of the suprarenal glands as a result of inanition arising from starvation, complete or partial. It may be that the suprarenals hypertrophy at the expense of the other endocrine organs, and by their increased function give rise to dropsy. Possibly also, this hyperactivity may in time give place to a suprarenal insufficiency, as exophthalmic goiter gives place to myxedema. This second condition may be pellagra. Whatever the true explanation may be, it is extremely probable that food deficiency, together with disordered function of certain endocrine organs, plays a large part in the causation of epidemic dropsy and pellagra.

Treatment of Gonorrheal Rheumatism by Vaccines Given Intravenously.—Fraser and Duncan think that giving vaccines intravenously secures a greater protection and that almost at once. The mechanism would seem to consist of a selective stimulation of the hemopoietic system by nonspecific bodies. Probably no single factor is responsible for all the changes that occur, but the intravenous injection upsets the balance of the serum constituents, and the series of changes thus caused establishes a condition favorable to recovery from infection. The vaccines they used had been stored for some months after their preparation, and they were, therefore, probably more or less detoxicated. Whether a detoxicated vaccine has any specific properties or not requires proof. They suspect that a vaccine minus its endotoxin consists simply of nonspecific proteose in a colloidal form. Clinically, they seemed to get the same results from injections of T. A. B. vaccine as from a gonococcus or mixed vaccine. The chief reason for using a gonococcus vaccine was that a supply was available, and its use afforded a great facility for graduating dosage. Freshly prepared typhoid vaccine often causes so severe a reaction that they would not risk giving it intravenously. Injections of endotoxins always produce toxic symptoms with but little or no increase of antibodies. Marked improvement followed in all of the fifteen cases treated. No benefit seemed to result from an injection that was not followed by pyrexia. At the time treatment was commenced, the patients were extremely debilitated with a rather fast and weak pulse, which was easily accelerated. The injections were all intravenous. The vaccines used were not freshly prepared. As a result of storing probably the toxins contained had broken down more or less. The injection of these, possibly nonspecific germ constituents, would seem to have caused the production of specific antibodies. The size of the doses used, compare favorably with the doses recommended by Thomson for his detoxicated vaccines. The largest dose of gonococci was 2,000 millions.

A New Pylorus.—Gillon does a posterior gastrojejunostomy with jejunoejejunostomy as a routine in all cases of pyloric

obstruction whether duodenal or pyloric or chronic gastric ulcer. The results are said to be uniformly good, and the patients are not only well, but very well. They put on weight. They develop a great capacity for swallowing large quantities of liquids without discomfort.

- *Recrudescence of Lethargic Encephalitis. A. Netter.—p. 45.
*Desiccated Eggs. A. Sartory and L. Flament.—p. 46.

Lethargic Encephalitis.—Netter states that in less than six weeks he has encountered twelve cases of lethargic encephalitis and knows of twenty other cases. They come from different parts of the city. Fever and somnolency were noted in every case, but the motor center for the eye does not seem to be affected as constantly as when the disease was observed in 1918. Two of the patients recovered without sequelae of any kind and two died.

Bacteriology of Desiccated Eggs.—Sartory and Flament found a number of aerobic micro-organisms in the egg powders examined, but no anaerobes. They warn that unless the desiccation is complete, these powders invite molds, etc. In making omelets or similar dishes the cooking will sterilize the egg powder, but when used for such dishes as ice cream, there is reason to fear the contamination inevitable with the present mode of packing and handling.

- *Motor Plastic Amputations. T. Tuffier.—p. 51.
*Plague and Leprosy in the Bible. Boinet.—p. 57.
*Dose of Ultraviolet Rays in Therapeutics. H. Bordier.—p. 59.
*Modern Treatment of War Wounds. H. Reynès.—p. 62.

Motor Plastic Amputations.—Tuffier expatiates on the sound principles involved in modeling the amputation stump to form loops, etc., which permit volitional control to some extent of the prosthetic appliance. In his recent trip to Italy he studied this cinematization and its results in the home of the method. The muscular force that these loops can exert is remarkable. In the leg, for example, he was unable to prevent the contraction of the loop even by applying all the force in his fingers. In the forearm and arm, the muscular power in the cinematized sets of muscles was also remarkable. Under the influence of the contraction of the loop in the stump, the fingers of the artificial hand can be flexed enough to grasp an article. But this grasp is very weak; it represents only 5 or 10 per cent. of this muscular force expended. The whole question and the future of these motor plastic operations depend on whether the prosthetic appliances can be perfected to transmit the muscular force in its entirety, or at least prevent such wasteful loss of power as at present. The prehensile force of the artificial fingers, even now, is enough for holding a pen or cigarette, wielding a fork, and lifting the hat, but in none of the cases he examined was there power enough in the fingers for manual work. However, the results already accomplished are a great gain for professional men, especially after bilateral amputation.

At the Rizzoli clinic at Bologna, Putti presented fifteen men who had been cinematized from six months to three years before, and at Milan Galeazzi gave demonstrations with ten others. Among them was one mechanic who was working a strong steel clamp with the cinematized biceps and triceps of his right arm, eighteen months after amputation of the arm. The precision of his movements was remarkable, and the clamp already showed signs of wear. Absolute fixation of the prosthetic appliance on the stump is indispensable to approximate natural conditions. The motor plastic operations are simple and easy. It may yet be possible to utilize separate muscles separately, and thus restore the play of the active and the antagonist muscles, instead of depending on the whole group at once. Surgeons must aim in their amputations henceforth to save as much as possible of the skin and soft parts, sacrificing the esthetic aspect of the stump to leave enough muscle and tendon material for ulterior and active utilization of the muscular force left in the stump. In conclusion Tuffier remarks that

no mechanical genius has as yet concentrated his attention on prosthetics, and the appliances in use are still clumsy.

Plague and Leprosy in the Bible.—Boinet's quotations show that the connection between bubonic plague and rats was known to the ancient Hebrews, and he ascribes to leprosy Job's "sore boils from the sole of his foot to his crown." The makers of false antiques in Palestine offer tourists silver mice which they claim to have excavated.

Unit for Ultraviolet Ray Doses.—Bordier utilizes for his unit the action of the ultraviolet rays on silver nitrate. This chromo-actinometer unit, as he calls it, corresponds to the quantity of ultraviolet rays which are able to reduce 1 mg. of silver to the square centimeter in a tenth-normal solution of silver nitrate 1 cm. thick. He tests for this unit with blotting paper impregnated with a 20 per cent. solution of potassium ferrocyanid. The color scale with this corresponds to 0.5, 2, 6, 12 and 18 units of quantity, representing the slight erythem dose, the erythem followed by desquamation; the photo-epidermitis, and intense photo-epidermitis. The 18 unit dose represents actual photodermatitis. He found with this color scale that a current of 6.5 amperes corresponded to 1 unit; 6 amperes to 0.8 unit; 5 amperes to 0.5 unit, and 4 amperes to 0.3. An old mercury vapor lamp yields only 0.5 unit while a new lamp yields 3 units during the same period of exposure. With this unit, he remarks, there is no further need for empiricism and guesswork in dealing with ultraviolet rays.

Modern Treatment of War Wounds.—Reynès presents data to prove that as early as November, 1914, he introduced in his service the method of clearing out at once all the devitalized tissues in a war wound, and thus claims priority for this method, which was generally adopted later.

Bulletins de la Société Médicale des Hôpitaux, Paris

*Glandular Functioning. H. Claude and S. Bernard.—p. 1116.
Share of Neo-Arsphenamin in Jaundice. H. Eschbach.—p. 1120.

Multiple Syphilitic Bone Lesions.—In the case reported by Gilbert and Saint Girons, in a woman of 52, there were seven foci of necrosis of bone, in the skull, radius, ulna, metacarpus and sternum.

Familial Amyotrophy.—Three sisters between 25 and 32 present different degrees of what Crouzon and Bouttier describe as a new variety of amyotrophy. The first symptoms appeared at 14, 22 and 12 years of age, and the older sister is unable to stand on account of the motor and atrophic disturbances. The speech is also spasmodic and panting, scarcely more than a whisper; the reflexes are abnormal, and there are choreiform movements.

Alcoholic Meningitis.—The subacute meningitis was explained by the alcohol found in the cerebrospinal fluid in the woman of 45. The symptoms were those of typical meningitis; syphilis and tuberculosis could be excluded, and the alcohol alone seemed to be responsible.

Tests of Endocrine Functioning.—Claude and Bernard have been giving organ extracts to healthy subjects and to those with various endocrine disturbances, seeking by these biologic tests to throw more light on the functioning of the different glands with an internal secretion. The responses differed widely from the normal after injection of pituitary extract in exophthalmic goiter, in hypothyroidism, and with suprarenal insufficiency. The different results obtained with organ extracts in different cases are readily explained by the varying preceding conditions in some of the endocrine glands. Among the practical results thus learned is that preliminary administration of thyroid extract or gland tissue enhances the action of the pituitary and suprarenal extracts.

Journal de Médecine de Bordeaux

- *Surgery on Native Africans. L. Verdet.—p. 7.
Pulmonary Sequelae of Mustard Gas Poisoning. H. Mallié.—p. 9.
*Hydrocyanic Acid. Chelle.—p. 14.

Surgical Experiences with Natives of French Colonies.—Verdelet was impressed with the extraordinary tendency to suppuration displayed by Africans on the slightest provocation. Suppurating hepatitis was common, and any lesion was liable to set up suppuration and cause the flaring up of old malaria or the onset of new, while the malaria in turn impeded the healing of the lesion. The malaria sometimes appeared disguised as acute appendicitis, orchitis, peritonitis or arthritis. He mentions further the ocular complications of malaria, and urges the advisability of preparing the subject for any operation by a preliminary course of quinin.

Toxicology of Hydrocyanic Acid.—Chelle reports experimental research which demonstrated that hydrocyanic acid and the alkaline cyanids become transformed under the influence of putrefaction processes into sulphocyanic acid. This is reversible under the action of a suitable oxidizer. After the death of a dog that had died ten minutes after taking 20 c.c. of a 1 per cent. solution of potassium cyanid, the organs were examined for hydrocyanic acid the second hour, and the eighth and thirteenth day. It had all disappeared, having become transformed to sulphocyanic acid, but it was easily transformed back again. This may prove useful in suspected cases of hydrocyanic poisoning.

Journal d'Urologie, Paris

*Anatomic Results of Prostatectomy. L. Phélip.—p. 353.

*Prolonged Hematuria with Calculi. L. Escudé.—p. 381.

*Hematomas of the Spermatic Cord. J. Martin.—p. 387.

Anatomic Results of Prostatectomy.—Phélip has collected sixty cases in which necropsy (twenty-five cases), a second operation, or cystoscopy plus radiography disclosed the conditions left by the prostatectomy. They explain the recurrences in some cases; a second operation is generally successful, and completes, he says, "the fine anatomic findings after operations for hypertrophied prostate, whatever the route." In only two cases was a fistula left where the rectum had been injured during a perineal operation shortly before. In all the others with a fistula it had solidly healed.

Prolonged Hematuria.—Escudé reports four cases in which hematuria appeared suddenly without known cause, and without pain; it kept up during repose the same as when up and about; was refractory to all medical measures, and persisted for weeks and even months without much impairment of the general health, and it sometimes subsided and reappeared capriciously. The only clue to its nature was some incident in the past suggesting lithiasis or the roentgen discovery of a calculus. The influence of congestion was evident in some of his cases, as also in Hartmann's case in which hematuria kept up while the boy of 14 was in a plaster cast. Necropsy three years later disclosed a large stone in the right kidney.

Hematoma of Spermatic Cord.—Martin had two cases of this rare pathologic condition in two negro soldiers within two days, but no cases of the kind before or since. No cause for the hemorrhage could be discovered.

January, 1920, 129, No. 1

*Operative Indications in Acute Appendicitis. E. Villard.—p. 6.

*Hysteric Paralysis. J. Froment.—p. 21.

Hysteric Paralysis.—Froment reiterates the importance of treating promptly and curing, usually in a few hours, hysteric paralysis, as otherwise it may drag along and become indelibly fixed. The opportunities for such "miraculous cures" as are possible with hysteria are too few and far between for any of them to be neglected. There is no use wasting time in seeking for stigmata of hysteria; the search is liable to impress unfavorable ideas. They are far from constant in hysteria, and the search for them may do harm by its effect as suggestion. It must be borne in mind that although hysteria may simulate all kinds of nervous disturbances, it

generally simulates them in an incomplete form, and the absence of certain phenomena which we have reason to expect in a given clinical picture will reveal its hysteric nature, and show that it is pure fiction, although unconscious fiction, and often sincere. The subject is merely the victim of a simple illusion. The paralysis varies in its intensity from moment to moment, and according to the act required, and it may disappear completely at certain moments. In some movement, for example, or some attitude, we may detect the intervention of some group of muscles which seemed before to be totally impotent. Such paradoxical findings, along with the anatomic and physiologic integrity of the limb affected, speak in favor of hysteria. It is important, however, to detect any associated organic disturbance which would hamper or annul the measures directed to the hysteria. The treatment requires on the part of the physician an inflexible will, patience, tenacity, kindness, iron energy; absolute confidence in the outcome, skill and self-possession. It is useless to reason with the patient. By varying the points of attack we seek to detect some movement in the paralyzed limb and convince the patient of his ability for movement, and start on from this for further progress. The hysteric paraplegic, for example, should be stood on his feet, and by aiding and making him walk, demonstrate to him that he can walk. Skill and tact are necessary to keep him from falling and from fruitless attempts, which confirm him in his conviction of his absolute paralysis. Sometimes it may take three or four hours to accomplish the result, but the session should not be concluded until some striking result has been attained, so that there can be no going back.

*Trephining in Glaucoma. A. Cantonnet.—p. 214.

*Iodin Treatment of Corneal Ulcer. A. Cantonnet.—p. 215.

French Ophthalmology, 1914 to 1920.—This entire number of *Médecine* is devoted to ophthalmology. Cantonnet lists among the lessons from the war the importance of fatigue and emotional stress in bringing on hemeralopia, and the frequent involvement of the eyes in dysentery, etc.: conjunctivitis and iritis in dysentery, keratitis and iritis in malaria, and recurring iritis in spirochetal jaundice. Similar complications ascribed to antityphoid vaccinations have been numerous, but analysis of them always disclosed a preexisting taint or predisposing factors or defective technic. The conclusion is obvious that the condition of the uveal tract should be ascertained before vaccinating against typhoid, especially subjects over 35 years old. He discusses further the disturbances in vision with pituitary enlargement, and the benefit from radiotherapy. Pituitary treatment may yield good results. If operative measures are necessary, access through the nose is less dangerous, and sometimes merely trephining the posterior wall of the sphenoidal sinus relieves the compression enough without exposing the pituitary. The cure of squint by exercising the eyes, without an operation, has been reported by several. Bailliart has invented an oscillogometer which, pressed on the eyeball, renders visible the pulse in the retina. Terson has added another sign to those in vogue for determination of actual death: One or two drops of a mixture of copper glycerolate and ethylmorphin glycerolate are instilled in the conjunctival culdesac. If life is still present, the conjunctiva turns red. New, also, Cantonnet adds, are the aviation tests for the velocity of the visual acuity, for nocturnal vision, and for vision facing sun glare.

Treatment of Gonococcus Ophthalmia in Adults.—Aubaret insists on the importance of rinsing out the eye thoroughly whenever pus reappears. Every two hours, day and night, the conjunctival culdesacs should be cleaned out with a

cotton pad, or with a douche can and glass cannula, using a tepid 1:2,000 solution of potassium permanganate, or 1:3,000 of mercuric cyanid. He describes further the specialist treatment, and warns the physician to use protecting goggles.

Suppurating Dacryocystitis.—Vacher and Denis describe how to clear out the purulent secretion in the lacrimal sac and to disinfect it with $\frac{1}{3}$ c.c. of chromic acid in a 1:50 solution, injected by the inferior canaliculus while an assistant at the same time instills hydrogen dioxide into the eye to neutralize any excess of the acid. After allowing two or three minutes for the acid to act on the lacrimal passages, he rinses them out with hydrogen dioxide. Preliminary cocaineization of the eye and lacrimal passages is necessary, and mechanical clearing out of the inferior canaliculus. The following days the eyelids and eyes are laved in hot water, squeezing out the contents of the lacrimal sac by pressure on the internal angle of the eye. This cauterization with chromic acid has often rendered dacryocystectomy unnecessary in their experience, while it has always proved harmless and effectual.

Foreign Bodies in the Eyes.—Vinsonneau says that any practitioner can remove a foreign body from the eye if it is not embedded too deep and is recent. When it is located deep or has been in the eye several days, he should not attempt its removal, but send the patient at once to the specialist.

Harvest Keratitis.—Chenet warns that the slightest excoriation of the cornea when there is an infectious process in the lacrimal passages is liable to induce a serious corneal ulcer. Eleven such cases were recently under observation during harvest time, all requiring surgical measures, and all impairing vision to a certain extent. All the men had chronic lesions in the lacrimal passages.

Dilation of the Orbit.—Jeandelize stretches the too narrow orbit by progressive dilation with vulcanite casts of increasing sizes, made from a paraffin cast.

Iodin Applied to the Cornea.—Cantonnet reiterates that the cornea tolerates perfectly a 1:20 or 1:30 tincture of iodine, after preliminary application of 3 or 4 per cent. cocaine. The iodine is taken up on a probe or glass rod and is held in the air for a minute or two to give the alcohol time to evaporate. Then the corneal ulcer is touched with it. The iodine cannot diffuse, as it is almost solid, and the conjunctiva thus escapes. The tincture should be less than 15 days old.

*Tuberculosis of the Spine. J. Calvé.—p. 13.

*Electro-Optic Rectoscope. D. Pamboukis.—p. 15.

Tuberculosis of the Spine.—Calvé insists that operative measures are useless and harmful in the early stages of Pott's disease in children. On the other hand, they are directly indicated in adults in the same conditions, as adults do not possess the faculty of spontaneous complete recovery which is peculiar to childhood. Orthopedic treatment with immobilization for three or four years results in complete consolidation in children, but the adult spine requires support as it never regains its full strength. The child with Pott's disease should be given general treatment for tuberculosis as well as the local orthopedic treatment. The organization of enough sanatoriums to allow this is the solution of the problem. For adults, the slight tendency to destructive processes and the lack of compensating processes are further reasons for reinforcing the spine by a grafting operation. He gives an illustrated description of his modification of the Hibbs technic. He makes a bed for the implant by cutting out the spinous process, leaving a right-angled cavity. Then he splits the lamina to each side, to the base of the transverse process, and turns back the piece thus pried up. This leaves a long, large freshened bed in the diseased vertebrae and in the sound vertebrae above and below. This gives a solid hold for the implant. The spinous processes resected are cut up into small pieces and are scattered along the whole length of the graft. This does away with the objections to the ordinary Hibbs method, which seems to

be better adapted than the Albee method to the dorsal region. Lower than this, the Albee technic has given fine results in his hands. The article is illustrated.

Rectoscope.—The four branches of Pamboukis' rectoscope spread apart after the instrument has been introduced closed. One branch is graduated, and the electric light is shielded from the eyes, while a telescope system magnifies the findings.

*Dextrocardia and Dextroversion. H. Vaquez and Donzelot.—p. 41.

*Albumin Content of Cerebrospinal Fluid. Ravaut and Boyer.—p. 42.

*Aseptic Pleural Effusion after Influenza. G. S. Coskinas.—p. 43.

Dextrocardia and Dextroversion.—Vaquez and Donzelot report two cases in which the long axis of the heart pointed to the right side, and yet the electrocardiograms were normal. Inversion of the cavities of the heart is the result of abnormal embryonal development, but when there is not inversion of the cavities, then the mirror aspect of the heart is always merely a mechanical displacement, with or without secondary malformation of the orifices. This seems to be the condition in these cases, both being apparently merely instances of congenital dextroversion of the heart.

Albuminimeter.—Ravaut and Boyer estimate the percentage of albumin in the cerebrospinal fluid by comparing the opacity of the fluid with that of a mixture of a solution of silver nitrate and of sodium chlorid. Two test tubes are graduated specifically for the calculation, and the whole procedure takes only a few minutes. The findings are as exact, they declare, as with any of the current methods, and no more than 1 c.c. of the spinal fluid is required for the test.

*Intradermal Urine Test for Tuberculosis. F. Miche.—p. 567.

*Case of Codein Poisoning. L. Boissonnas.—p. 581.

Protracted Peritonitis from Typhoid Perforation. P. Gautier and P. Brutsch.—p. 587.

Vincent's Angina Simulating Hard Chancre. G. Cornaz.—p. 591.

Intradermal Urine Test for Tuberculosis.—Miche has simplified the technic for using urine from a tuberculosis suspect in place of or to control the tuberculin test, and reports that the findings paralleled those with the latter test in seventeen cases in which both were positive, and in four cases in which both were negative, but in four other cases they conflicted. With the urine extract the reaction is more pronounced in the very active cases, and it is weak in the cases with a more favorable prognosis, thus throwing light on the outcome. He explains this by the fact that the urine is a tuberculin-antituberculin, more potent in the more active cases. He evaporates fresh urine and uses the desiccated urine with 2 c.c. of distilled water, forming a 10 per cent. solution, and applies it for the test by the skin or the intradermal tuberculin technic.

Case of Codein Intoxication.—The boy of 3 was given 0.04 gm. of codein by mistake for calomel. There were no symptoms for forty-five minutes, then intense headache, stiffness and unconsciousness, imperceptible pulse, contracted pupils, and stiffness of the neck, the head thrown back, testified to the severity of the toxic action. The muscles in the legs were relaxed. The heart was beating at 120 and râles were heard at the hilum. Half an hour after a tepid enema and injection of camphorated oil, the child became conscious. The injections of camphorated oil were continued every two hours, and wet cups were applied to the dorsolumbar region, and the child was made to drink freely of black coffee;

diuretic teas and mineral waters. There were several convulsions but the symptoms had all subsided in three hours except for anuria and drowsiness. The anuria persisted for two days; the distended bladder was punctured the first evening, and 400 c.c. of urine withdrawn, as repeated attempts to introduce the catheter had failed. The nature of the substance given in place of the supposed calomel was not known until after several hours, the sugar with the powder interfering with the chemical tests. The literature on codein poisoning is reviewed. The loss of consciousness is constant in such cases; if this stage does not end in the fatal collapse, agitation, vomiting and gastralgia, convulsive movements and exaggeration of the reflexes are the usual symptoms. Dilation of the pupils was noted in some cases and contraction in others. In dogs, the narcotic stage is accompanied by miosis which changes to mydriasis in the stage of agitation. Retention of urine has been noted with 0.1 to 0.2 gm. of the drug.

*Symptoms from Cavity in Child's Lung. C. L. Rusca.—p. 23.

*Spina Bifida. R. Vaglio.—p. 33.

Symptoms from Cavities in the Lungs in Children.—Rusca expatiates on the misleading findings with a cavity in a child's lung, as the walls and tissues are so elastic that the vibrations are transmitted to remarkable distances. There is actually no absolutely pathognomonic sign of a cavity; the presumptive signs have to be considered in connection with the roentgen findings.

Spina Bifida.—In the last six years twenty-three cases of spina bifida have been under treatment at the children's clinic in Naples. In one case it was double, both cervical and lumbar; in another, the tumor returned as hydrocephalus developed after the operation for the spina bifida. In 52 per cent. there were other malformations; inherited syphilis was manifest in 39 per cent. This suggests the advisability of specific treatment preliminary to operation when there is the least suspicion of the inherited taint. Vaglio thinks it is wiser to defer operating for spina bifida until the infant is a little older, unless one's hand is forced.

*Extra-Uterine Pregnancy at Term. P. Nubiola.—p. 433.

Radium Treatment of Uterine Cancer. Vital Aza.—p. 440. Cont'n.

*Delivery of Thoracopagus Monster. Roig-Raventos.—p. 449.

Delivery of Viable Child from Extra-Uterine Pregnancy.—Nubiola ascertained that the pregnancy was continuing apparently normally although the fetus had slipped into the abdominal cavity. The woman was kept under surveillance, and was delivered by a laparotomy at term. The left tube was adherent to the membranes; the ovum had probably been embedded primarily in this tube. It was resected, and the placenta was separated by hand—a most tedious task as it was attached besides to the posterior surface of the uterus, the Douglas pouch, to portions of the rectum and cecum and to several loops of the bowel. Step by step, with numerous ligatures, the placenta was pried loose, leaving an extensive raw surface with merely slight oozing of blood. The child seems to be normal, and at 4 months weighed 5 kg. Marsupialization and abandoning the membranes and placenta may be required in exceptional cases, but only when conditions are too grave to remove them at once. Nubiola reviews what others have written on the subject, including Harris' thirty cases (1888) and R. Costa's monograph (1915), and nine in recent Spanish literature. In his case he irrigated the abdominal cavity by the Carrel-Dakin method, commencing the seventh day when the temperature had begun to rise. At the third week a scrap of gangrenous membrane tissue was expelled, and, after this, recovery was soon complete.

Thoracopagus.—Roig-Raventos describes the maneuvers necessary for extraction of the united twins. The membranes had ruptured four days before. The cause of the obstruction

to delivery was not recognized until the united trunks came into view. The total weight was 7,500 gm. and the placenta weighed 1,800 gm. When he saw the case there was no circulation in the cord, and evisceration aided delivery.

*Morphology of Spleen Tumors. Y. Nishikawa.—p. 1.

Morphology of Spleen Tumors.—Nishikawa's monograph fills the 216 pages of the issue, and is accompanied by twenty-nine photomicrographs and a bibliography of the titles of 154 articles. The morphology is compared of the various chronic tumors of the spleen, enlargement with malaria, cirrhosis of the liver, leukemia and simple congestion of central or peripheral origin, syphilis, schistosomiasis and Banti's disease—a total of 116 cases. The regular and even fibrous degeneration of the spleen in Banti's disease is so constant and so extreme that it may be regarded as almost pathognomonic. The enlarged spleen is the primary site in this disease, and consequently splenectomy is the rational treatment of Banti's disease. The characteristic microscopic findings in this and other diseases are compared in fourteen folding tables, the cases listed under eighteen headings, including the blood and marrow findings, duration, and various clinical symptoms.

*Stages of Pulmonary Tuberculosis. K. Engelmeier.—p. 1014.

*Tuberculosis of the Larynx. J. W. Samson.—p. 1018.

*Erythema Dose in Hard-Ray Roentgenotherapy. F. M. Meyer.—p. 1020.

Increasing Spread of Quackery. Neumann.—p. 1021.

Comparative Investigations with the Wassermann and Sachs-Georgi Tests.—Raabe reports the results of a series of comparative Wassermann and Sachs-Georgi tests, and gives a detailed description of the modified technic for the latter. It is applied with physiologic sodium chlorid solution and natural cholesterinized organ extracts. Of the 1,750 parallel tests, 569 were positive by both the Wassermann and the Sachs-Georgi reaction, while 1,005 cases were negative by both tests. Of the 569 positive cases, 519 had been clinically diagnosed as unquestionably syphilis. In view of the close agreement between the results secured by the two methods, the writer concludes that, from the standpoint of diagnosis, therapy and prognosis, the Sachs-Georgi precipitin test deserves ample recognition, but she does not think that it can be regarded, even with its simplified technic, as a substitute for the Wassermann reaction. Its value as a control of the Wassermann reaction is, however, already established.

The Clinical Value of Recent Classifications of the Stages of Pulmonary Tuberculosis.—The clinical need of a practical classification of the various stages of pulmonary tuberculosis has long been felt and many attempts at classification have been made. Engelmeier describes in detail several methods of classification and the principles on which they are based. He favors Ranke's classification, who, he thinks, is without doubt on the right track, in that he considers not only the organ in question—the lungs—but also the behavior of the whole organism. Ranke's views need, however, further elaboration and confirmation in order to make them more valuable to the practicing physician. More important than the classification of the disease is the proper evaluation of the patient. We must remember that we are not treating a disease, but a sick person.

Tuberculosis of the Larynx.—Samson confirms previous reports that the increase in tuberculosis during the war period in Germany has been very marked. This has attracted the attention of all concerned to the various complications under which the disease appears, and Samson finds that our views with respect to tuberculosis of the larynx, especially, need some revision, owing to the exceptional danger of infection from it. It is estimated that the percentage of

patients with laryngeal tuberculosis whose sputa contain tubercle bacilli is twice as great as the number of patients with pulmonary tuberculosis of whom this is true. According to Binger the proportion is even greater (75.8 per cent. as compared with 30 per cent.). These figures show the great importance of measures for the protection of the patients' families and the general public. For the purpose of early diagnosis of tuberculosis of the larynx, which thus becomes imperative, it is desirable that the lung specialist should also be a throat specialist. Samson emphasizes the need of isolation of such patients in the family, as the danger of spreading the infection is a thousand times greater than in the case of pulmonary tuberculosis. With the latter, care in collecting and disposing of the sputum will accomplish much in the way of prophylaxis, but with tuberculosis of the larynx such care is in vain, owing to the danger of infection from sudden coughing spells and the increased respiratory effort in speaking, as has already been pointed out by Friedrich. The need of isolation applies to hospitals and sanatoriums as well as to families.

Erythema or Normal Dose in Hard-Ray Roentgenotherapy.—Meyer is convinced that widespread uncertainty exists as to what constitutes an erythema, or normal, dose in hard-ray roentgenotherapy. He thinks this uncertainty is due to the fact that formerly roentgenotherapy with medium soft rays prevailed, and that here there was an accidental correspondence between the desired biologic effect and the effect on a certain chemical substance—barium platinocyanid—in a dosage that produced a certain definite coloring, known as Tint B, when applied to a patient caused an erythema of the skin (allowing, of course, for idiosyncrasies and the fact that certain parts of the body—the face, for instance—are more sensitive than others). Meyer fears that these same conditions are still being applied by some to the hard-tube irradiation, with the result that, from a practical standpoint, the technic is defective and too small doses are given. The harm lies not only in the fact that patients are thus deprived of the maximal benefit, but also in the added fact that in the treatment of malignant growths an underdose, instead of paralyzing or destroying malignant cells, may be just suited to incite them to increased proliferation. Meyer states further that if a disease does not react to one form of irradiation, one should not assume on that account that it will not react at all. A change in our therapeutic program and our technic will often bring about the desired results.

Gas Cysts in Brain from War Wounds. Goldammer.—p. 86.
Emergency Treatment of War Fractures. O. Braun.—p. 100.
Ileus from Shellac in Small Intestine. W. Bellmann.—p. 127.
*Dislocation of First Tarsometatarsal Joint. Girgensohn.—p. 135.

Surgery of Gastric and Duodenal Ulcers.—Troell reviews the experiences at the Serafimer Hospital at Stockholm since 1907 with operative measures for gastric and duodenal ulcers, a total of 234 cases, and compares them with results reported by others. His bibliography includes 191 works. Multiple ulcers were found in 5 per cent. There was appendicitis in only 9 cases, and gallstones only in 2. The time of onset of the pains did not correspond infallibly to the location of the ulcer, although there was some evidence which suggested that the degree of the acidity or disturbance in motor functioning determined the character of the pains. Pronounced hyperacidity with an extrapyloric ulcer may induce pains like those of a juxtapyloric ulcer. On the other hand juxtapyloric duodenal ulcers may induce pains of the extrapyloric gastric ulcer type. He queries whether this is a general rule or not. In many of the cases there had been no pains or they had been slight. He queries further whether there is any special region in the stomach where ulceration never induces pain. Attenuation of the pains on change to reclining on the left side was noted with 3 extrapyloric gastric cancers; 3 patients were relieved by lying down; 1, with a duodenal ulcer, by standing up. In 26 cases, including 11 extrapyloric gastric ulcers, the pains were relieved by

eating something; in 38 cases, by vomiting. A connection with constipation was evident in a few cases, the pains being relieved by defecation. There had been diarrhea in 27 cases. The symptoms that never proved misleading included tenderness over the duodenum, the protruding or receding pocket, the air bubble at the top of the duodenum, the retraction in the wall at one point, and rapid passage of the chyme through the duodenum, or antiperistalsis. But displacement of the pylorus to the right may occur with gastric ulcer, and the chyme may linger in the duodenum.

The mortality of the ulcer operations was 8.5 per cent. before 1916 and 6 per cent. since then, mostly from peritonitis and lung complications. Troell's conclusion from the gastric ulcer cases is that resection, with gastro-enterostomy, guarantees best complete recovery, and this without any more operative risk than gastro-enterostomy alone. This applies both to transverse and to segmental resection, plus the gastro-enterostomy. All this material is tabulated under various headings, as also the roentgen findings in 64 cases, reexamined later. The latter group teach the necessity for making the gastro-enterostomy well toward the right to avoid production of a blind pouch. Another point learned is the unreliability of measures to shut off the pylorus, and it is a question whether there is any use in attempting it. The experiences related show further the possibility of secondary hour-glass constriction of the stomach after terminal suturing together of the stumps. In 13 per cent. of the total ulcer cases, with long survival, the operation did not improve conditions. This group included 10 per cent. of the hour-glass stomach cases; 10 per cent. of the antral gastric ulcer cases; 10 per cent. of the pyloric duodenal ulcers, 11.5 per cent. of the extrapyloric gastric ulcers; 20 per cent. of the extrapyloric duodenal ulcers, and 41 per cent. of all the cases with dubious operative findings. Thus, no improvement followed the operation in 41 per cent. of all the cases with inconclusive operative findings, and this teaches, Troell declares, the advisability of refraining from any operation when the exploratory incision fails to show any crater, scar, or other evidence of ulcer.

Dislocation of the First Tarsometatarsal Joint.—Girgensohn advocates immediate reduction, giving the roentgen findings in a case. A fall from a horse is the most frequent cause of the luxation. The prognosis is good with proper treatment.

Habitual Dislocation of Patella. F. Lückeroth.—p. 236.
Irrigation Treatment of Inflammation in Abdominal Cavity. J. J. Stutzin.—p. 265.
The Murmur in Aneurysms. A. Israel.—p. 281.

Gastric and Duodenal Ulcer.—Reinhard devotes ninety pages to a critical summary of the experiences at the Hamburg clinic with 68 cases of gastric ulcer; 36 of pyloric; 33 of duodenal and 13 of dubious duodenal ulcer with 9 cases of cicatricial stenosis of the pylorus. The symptoms and clinical picture in practically all pointed unmistakably to ulcer, but not to its location. The symptoms with gastric ulcer were often those supposed to be typical of duodenal ulcer and vice versa. Palpation gave instructive findings in 79.8 per cent. but not as to the location. The chemistry of the stomach was normal in nearly 50 per cent. Roentgen findings were conclusive as to the ulcer but were not always a reliable guide to its site.

Nederlandsch Tijdschrift v. Geneeskunde, Amsterdam

- *To Prevent Loss of Vitreous Fluid. J. van der Hoeve.—p. 1426.
*Testing Permeability of Lacrimal Canal. G. F. Rochat.—p. 1429.
*Metastatic Sarcoma in the Eye. G. ten Doesschate.—p. 1432.
*Refraction in Semidarkness. F. Wibaut.—p. 1437.
*Syphilis of the Stomach. G. O. E. Lignac.—p. 1441.
Emergency Tracheotomy on Account of Goiter. H. van der Tak.—p. 1448.

To Prevent Loss of Vitreous Fluid in Operations on the Eyes.—Van der Hoeve gives an illustrated description of the four threads method with which he lifts up the anterior wall of the eyeball. The vacuum made by lifting up the wall aspirates back any of the vitreous fluid that is on the point

of escaping. Each thread is passed through the outer layers of the cornea, close to the iris, to form four loops with which the two assistants lift up the wall when loss of the fluid is impending. The loops are useful also for other purposes, as he describes.

Test for Permeability of the Lacrimal Canal.—Rochat comments on the difficulty sometimes experienced in determining whether the lacrimal canal is normally permeable, as the pressure required to force fluid through the canal varies so widely. His own research seems to show that the pressure required in normal conditions is from 17 to 22 cm. water. When greater pressure than this is required, the lumen is certainly pathologically narrow.

Metastatic Sarcoma in the Eye.—Ten Doesschate reports a case, in a woman of 49, of primary melanosarcoma in the right eye with multiple metastases, including one in the left eye. In a second case, a woman of 50, a pigmented nevus below the right breast became transformed into a sarcoma, and was excised in 1914. In 1917 metastases developed in the brain and skin and in the uvea of one eye and in the retina of the other eye, but the papilla escaped. He does not know of any record of similar metastasis in the retina from a tumor elsewhere. A few cases are cited of metastases in the eye from sarcomatous degeneration of a nevus on the cheek, parotid region, etc., but none were on the retina. Primary sarcoma in both eyes has been reported by Fuchs and five or six other writers.

Refraction in Semidarkness.—Wibaut asserts that the refraction increased by 0.5 to 1.5 D in semidarkness in seven persons tested. Charpentier reported eighteen years ago that myopia becomes exaggerated in the dark; he found differences up to 3 D in some, and in himself up to 2 D. Wibaut explains the mechanism of this.

Syphilis of the Stomach.—Lignac resected the middle third of the stomach for supposed cancer in a man of 52, and the latter has been in good health during the nine months to date, but the resected portion showed merely chronic gastritis, gummas and syphilitic ulcers, no signs of malignant disease. Dubuc gave specific treatment in a case of supposed cancer of the stomach and the results were excellent, as also in several of Fenwick's cases of supposed gastric cancer. Lignac queries whether we ought not to rank gastric syphilis beside ulcer, gastric cancer, and gastric crises in studying puzzling cases of pathologic conditions in the stomach. The absence of tertiary manifestations elsewhere should not exclude syphilis. This lesson was taught by the case here reported in which there was nothing to suggest syphilis before the operation; even the Wassermann test was negative. Benefit from specific treatment should be evident in five days, but relapses are liable. The great danger is hemorrhage from an eroded vessel. Fränkel has reported a case of peritonitis from perforation of a gummatous ulcer. In Nathan's case, mercurial treatment of a tertiary syphilitic lesion on the arm cured at the same time pathologic conditions in the stomach which had been causing symptoms for ten years. The pains may be severe, especially at night, and the clinical picture in general may simulate gastric ulcer, cancer or tabetic crises.

Hospitalstidende, Copenhagen

Jan. 7, 1920, 63, No. 1

*Bromid Infusion in Psychoses. C. Jørgensen.—p. 12.

Bromid-Saline Infusion in Treatment of Psychoses.—Jørgensen relates that bromid by the mouth has not been satisfactory in the treatment of psychoses in Jacobsen's service. Since they have been giving it by the subcutaneous route, the results have been immeasurably better. They give it in saline infusion, and assert that this treatment is more potent in controlling maniacal attacks than any other simple and harmless measure known to date. The mother solution is made with 150 gm. sodium bromid; 7 gm. calcium chlorid; 3 gm. potassium chlorid, and distilled water to 300 c.c. For the infusion they use 20 or 30 c.c. of this solution in a liter of water. It is thus a slightly hypotonic or isotonic saline solution with a content of 15 gm. sodium bromid. This

infusion once or twice a day aids in combating the toxic factors responsible for the exacerbation, while the substitution of the bromid for the usual sodium chlorid in the saline solution has an exceptionally prompt sedative action. Nine cases are described to show the efficacy of this treatment, arresting convulsions and delirium. Some of the patients responded in cases refractory to the usual narcotics with a slight rise in temperature, and one, a previously healthy woman of 46 with acute mania for a week, developed a slight and briefly transient collapse condition after one of the bromid-saline infusions, but she also had the same after an ordinary saline infusion. As 103 gm. sodium bromid is the equivalent of 58.5 gm. sodium chlorid, the solution used is equivalent to an ordinary 8.5 per thousand solution of sodium chlorid. In the two latest cases they gave 80 gm. and 105 gm. of the bromid in the course of four days, and the acute mania subsided.

Jan. 14, 1920, 63, No. 2

*Cholelithiasis and Achylia. F. Rydgaard.—p. 17. Begun No. 1, p. 2.

Cholelithiasis and Achylia.—Rydgaard found achylia in 47.4 per cent. of Rovsing's operative gallstone cases, and in 52 per cent. of a total of 471 cases compiled, including the Rovsing cases in 26 men and 132 women. The sex and age do not seem to influence the achylia, but 74 per cent. of the 135 patients with stones obstructing the cystic duct had achylia or hypochylia. In some cases the achylia developed as the cystic duct became obstructed, showing the special dependence of the former on the latter. It seems plausible to assume that the incontinence of the sphincter papillae, which is so often entailed by the stretching of the cystic duct by the gallstones, upsets the physiologic process of the neutralizing of the acid stomach content by the bile. The former is poured out unneutralized into the duodenum, and the irritation of the duodenal wall from its acidity sets up reflex action which entails the achylia. When the sphincter is normal, there is no achylia notwithstanding the presence of gallstones. Other arguments are presented which sustain Rovsing's conviction that the gallbladder is a physiologically important organ, and that it should not be removed without imperative indications for this. Cholecystotomy is all that is necessary in many cases to cure both the gallstone disturbances and the achylia. Even if there should be recurrence of stones, this is not enough of a reason for removing the gallbladder, any more than the kidney under similar conditions. The experiences related and the theoretical reasoning all emphasize the necessity for early operative measures in cholelithiasis, getting rid of the stones before the cystic duct has been stretched to a degree that entails incontinence. An early operation also wards off achylia and, in warding this off, prevents infection. As soon as the first symptoms warn of the presence of gallstones, operative measures should be applied at once, Rydgaard reiterates in conclusion.

January, 1920, 81, No. 1

*Caesarean Section at Christiania. K. Brandt and C. Smith.—p. 1.

*Diet with Insufficiency of the Kidneys. K. Motzfeldt.—p. 13.

*Vital Staining of Nerve Cell and Its Consumption of Oxygen. G. H. Monrad-Krohn.—p. 36.

Pathologic Anatomy of Influenza and Its Complications. F. Harbitz.—p. 46.

Cesarean Section.—Brandt and Smith analyze the record at Christiania of sixty-two classical cesarean sections and forty vaginal in the last thirteen years in a total of 18,140 childbirths. In 87.5 per cent. the operative delivery was the last resort in eclampsia, and 80 per cent. of the women were saved by it; in 10 per cent. of the others, necropsy disclosed irreparable lesions of internal organs. Central placenta praevia was the indication for the classic section in two cases, with recovery in both. They regard vaginal section as irrational for placenta praevia; the difficulty is to recognize the central placenta in time.

Dietetic Treatment of Insufficiency of the Kidneys.—Motzfeldt insists that functional tests of the kidneys must be the guide for treatment, varying the diet to conform to the individual conditions at the time. He recalls that restriction

to milk in systematic treatment of Bright's disease was preached by Chrestien of Montpellier four years after Bright's publication. His motto was "Milk or death"; but we know now that abstinence from salt and a low protein diet are the essential features of dietetic treatment, and that milk does not conform entirely to either essential. Carbohydrates and fats can be disregarded and be allowed, free from restrictions, but the water balance, the mineral metabolism, and the nitrogen intake must all be studied and regulated according to the tolerance. Retention of salt may be a secondary phenomenon, and extrarenal factors probably play a large part in it, so that it is scarcely correct to speak of the kidney's "permeability for sodium chlorid." From the therapeutic point of view this is of minor importance, but it is still a question whether the sodium or the chlorid element is the responsible factor. Thorling regards the sodium as more directly influencing the water balance, so that attempts to substitute sodium chlorid with sodium bromid or citrate or other sodium salt are not rational. Motzfeldt warns against the routine use of a salt-free diet, saying that it has not fulfilled the anticipations roused by Vidal's cases, and even at the best, the conditions may be so grave that the strictest reduction may not have any effect. It should be given a trial, however, and be continued for several weeks. The outcome was most striking in one case of acute nephritis in a young man; on the salt-free diet he lost 27 kg. in weight in twenty-two days. He eliminated 250 gm. of chlorids in the urine, which corresponds to 27 liters of a 9 per thousand saline solution. Vidal has reported a case with loss of 28 kg. in seventeen days. Vidal regards 1.5 gm. as the ordinary sodium chlorid requirement, below which it is unwise to go for a long period; Romberg says that 5 gm. is the limit; Strauss, 2 gm. In uremia with convulsions, if the phenolsulphonephthalein test shows normal conditions, the protein intake need not be restricted. But otherwise a low protein diet is indispensable, down to 20 or 30 gm. temporarily; 50 gm. seems to be the lowest limit that can be borne for any length of time. Restriction of the protein reduces the uremia, attenuates the clinical symptoms, and renders the prognosis more favorable, as Motzfeldt shows by four cases. The effect can never be definitely determined beforehand, and it should always be given a trial, especially in the acute exacerbations of chronic nephritis. It may take several days for the effect on the uremia to become manifest. When the nitrogen content of the blood has been brought down to normal, the patient's tolerance for protein should be carefully determined. His charts give the protein intake curve, the degree of azotemia and the phenolsulphonephthalein findings curve. In conclusion he reiterates that the diet with kidney insufficiency should be determined and enforced with as much care as in diabetes.

Vital Staining and Oxygen Consumption of Nerve Cells.—Krohn describes Mott's recent research on the consumption of oxygen by nerve cells and the transformation of chromatomethylene blue into leukomethylene blue in the living nerve cell, and the reverse transformation when oxygen is supplied. In Mott's work on shell shock he explained how the smaller nerve cells are particularly susceptible to deprivation of oxygen, as they have so little reserve oxygen to draw on, in comparison to the larger cells.

*Hysteria in Children. Monrad.—p. 31. Begun in No. 1, p. 1.

*Torsion of the Omentum. H. O. Wildenskov.—p. 40.

*Inherited Neurosyphilis. K. Baagøe.—p. 42.

Hysteria in Children.—Monrad gives a brief review of the recorded history of hysteria in children, the etiology and the pathogenesis and then describes the extremely varied manifestations of hysteria in children. He emphasizes that in children it is monosymptomatic, that is, there are merely single or a few manifestations while there are none of the permanent symptoms, the so-called stigmata. Over 200 cases of hysteria in children have been encountered in his practice in the last ten years. It simulated in the different cases almost the entire range of organic pathologic con-

ditions in the nervous system, the urogenital and digestive apparatus, and the abdomen, besides various surgical processes. Numerous instances of each type are described and the treatment found most effectual. The prognosis of hysteria is far more favorable in children than in adults. Treatment has to be exclusively psychotherapy and this requires skill and tact, and usually removal of the child to some wholesome environment where he will not be the central figure. The transference to a hospital may make the child forget his hysteria completely. The psychotherapy may be masked with some local application to cause a little pain or shock, but the main thing is to impress the physician's authority on the child while convincing him that the doctor is his friend. Sometimes a child with astasia-abasia can be cured by standing him up on the floor and categorically commanding him to walk. A promised reward may aid in some cases. A sudden cold douche or electric shock on the region affected may succeed, but Monrad warns that when any of the above measures fails, it is useless to repeat it.

In a paroxysmal form of hysteria, systematic ignoring of the child often proved effectual; especially when the child was allowed to overhear the persons in the room speaking of what would have to be done to him if the attacks continued. Examination under a general anesthetic, besides roentgenoscopy and tuberculin tests, may be necessary to exclude organic bone disease. One little girl had a hysteric sacrocoxitis, others hysteric neuralgia in the knee, hip joint, heel or spine. There was usually a history of some trauma attracting attention to the region and the cure is often tedious then as the local measures applied had anchored the hysteria more firmly. In the case of one girl of 5 a specialist had diagnosed cervical spondylitis and insisted on orthopedic treatment. The symptoms became so alarming that the child was taken into the general hospital where the diagnosis was changed to hysteria from the negative tuberculin and roentgen findings, the history of pediculosis with impetigo and swelling of the glands in the neck, causing pain when the head was moved. The torticollis, etc., were only the hysteric prolongation of a previous reflex torticollis, and the cure was complete in a few weeks. In infants about a year old, hysteric anorexia may be connected with weaning or be a hysteric prolongation of some gastro-enteritis. Removal to another environment usually cures it at once. One girl of 11 had become so emaciated and weak from the hysteric anorexia that the pulse was only 40, respiration 16. Isolation in the hospital did not help until she was told that she would have to be fed through a "snake," the Danish word for "snake" and "tube" being the same. Then she began to eat normally until she coaxed an attendant to show her the "snake"; no more eating after that. Finally Monrad told the nurse in her presence that if she did not begin to eat soon she would get decubitus. The girl inquired about decubitus and was shown the large loathsome sores. This cured her anorexia, and she gained 1,900 gm. in weight in two weeks, but the anorexia returned a few months later. In three cases there were hysteric strictures in the esophagus. Hysteric vomiting is usually cured by removal from home, even when the vomiting has kept up for years. In five cases the hysteria simulated appendicitis, the children having heard older people describe the symptoms.

Torsion of the Omentum.—Wildenskov urges detorsion and resection of the omentum, saying that with this the mortality was only 4.5 per cent. among the 89 cases on record, exclusive of the 3 per cent. fatalities explained by other causes. In the personal case reported the diagnosis had been appendicitis. In 65 of 80 cases there was concomitant hernia, as also in his case. The long pedicle of the clump of omentum in his case had made six complete turns toward the left.

Inherited Neurosyphilis.—Baagøe queries as to the connection between the inherited syphilis and the imbecility plus the extreme backwardness; the aphasia; or the juvenile tabes, plus sudden blindness, in the three children described. Some of them testify anew to the fact that these severe forms of neurosyphilis from the inherited taint occur in the children of parents whose syphilis was so mild it escaped detection or was disregarded.

INTERPRETATION OF ROENTGEN-RAY FINDINGS IN THE DIAGNOSIS OF PEPTIC ULCER

SOME DIFFICULTIES*

C. W. McCLURE, M.D.

AND

LAWRENCE REYNOLDS, M.D.

BOSTON

One of the most important advances in the diagnosis of gastro-intestinal lesions has been the development and application of roentgenographic methods in this field. As is likely to occur when any method is devised which demonstrates new objective signs of disease, certain findings obtained by roentgen-ray studies create new diagnostic problems. Most important of the problems is the significance of roentgen-ray findings and their relative value, to those obtained by other procedures, in the diagnosis of gastric and duodenal lesions. These have been discussed in former communications.¹ Our purpose in this paper is to present some of the difficulties and errors into which roentgen-ray findings may lead in relation to the diagnosis of peptic ulcer.

Temporary muscle spasm occasionally produces distortion in the outline of the duodenum or stomach like that produced by an ulcer. An example of this condition is pictured in Figures 1 and 2. In this case the deformity pictured was present throughout one examination but absent in another made two weeks later, although the symptoms remained unchanged. When such deformities occur in cases in which the clinical findings are not those usual for peptic ulcer, the roentgen-ray studies should be repeated at a later date. At the second examination, especially if atropin has been given to the physiologic limit, the deformity usually will have disappeared. If this precaution is not taken, one may be forced erroneously to consider the presence of organic disease where it does not actually exist. This is illustrated in Case 1:

CASE 1.—Diagnosis, *gastric neurosis*.—F. R. G., white man, aged 32, salesman, with unimportant family and past medical histories, from February to November, 1914, had had attacks of slight dizziness with some nausea and occasionally vomiting, but no hematemesis, or bloody or tarry stools. The attacks recurred every two or three weeks and lasted for about half a day. In November, 1914, severe epigastric burn-

ing from two to three hours after meals began; this symptom persisted for two weeks. The patient was then placed on a diet by a New York physician, which was followed for several months with finally complete relief from symptoms. The patient remained well until the present illness, October, 1919. About the first of that month the onset of mild burning in the epigastrium, from two to three hours after meals, began. The symptoms gradually increased in severity until at the end of three weeks the patient sought medical advice. The appetite was good. There had been no vomiting. The bowels were constipated. There had been no loss in weight.

Physical examination was essentially negative.

Roentgen Report: The stomach was normal in position and tone. Its outlines were regular. There was active peristalsis, and the pyloric sphincter closed normally. There was constantly present a definite irregularity of the lesser curvature side of the first portion of the duodenum. Otherwise the duodenum appeared normal.

Interpretation: The findings are those usual in ulcer of the first portion of the duodenum.

Roentgen-ray studies were repeated in two days and again one month later. On both occasions the duodenum filled normally and its outline was regular.

Clinical Pathology: Gastric analysis was not made. The stools gave a negative benzidin test for blood. The usual examinations of the urine and blood were negative. The Wassermann reaction in the blood serum was negative.

Progress: Treated on the basis of a neurosis, without special dietary measures, the patient became free from all symptoms within one week. During this period he carried on business as usual. He remained well, while under observation, for the ensuing three months.

This case shows the value of cooperation between the roentgenographer and the clinician. The clinical history was not typical of ulcer, yet the first roentgen-ray findings were characteristic of that condition. The discrepancy led to a repetition of the roentgenographic examination. The result was such as to show that the first findings were transient, probably the result of temporary muscle spasm and not due to an ulcer.

There is a type of case in which a persistent duodenal deformity, resembling that due to ulcer, exists and yet is probably due to some cause other than ulcer, such as adhesions, congenital or acquired. Case 2 furnishes an example of this:

CASE 2.—Diagnosis, *duodenal ulcer*.—J. J. C., Med. No. 11061, white man, aged 47, expressman, admitted to the Peter Bent Brigham Hospital, May 12, 1919, and discharged, May 15, 1919, complained of distress in the abdomen. The past medical history was essentially unimportant. Gastric symptoms began seven years prior to admission. The symptoms had occurred in periodic attacks, usually at intervals of about every two months and persisting for from one to six weeks. The interval between the last two attacks had been one year. The last attack began three weeks before admission, and was of the same character as the preceding ones.

* From the medical clinic and roentgenographic department of the Peter Bent Brigham Hospital.

1. McClure, C. W.: Certain Diagnostic Aspects of Medico-surgical Diseases of the Gastro-Intestinal Tract, Boston M. & S. J. **181**: 399 (Sept. 25) 1919. McClure, C. W., and Reynolds, Lawrence: Gastric and Duodenal Ulcer: Typical and Atypical Forms; The Relative Value of Diagnostic Procedures, *ibid.*, to be published.

Dull, aching distress in the epigastrium occurred at variable periods of the day or night, and without relation to food except for a tendency to appear just before meals. The distress was partially relieved by food and to a greater extent by soda. Belching of considerable amounts of gas was a prominent symptom. The appetite was usually good. There

Fig. 1 (E. W., O. P. D. 60463).—Antral incisura, due to temporary muscle spasm, in a case of gastric neurosis.

had been no vomiting, no hematemesis, no jaundice, and no bloody or tarry stools. The bowels were regular. The patient was usually able to trace a connection between gastric symptoms and emotional stress, such as worry over business affairs.

Roentgen Report 14735 (Fig. 3): The stomach was normal in position, outline and tone. It was freely movable, and hyperperistalsis was present. The pyloric sphincter showed no abnormalities. The outline of the first portion of the duodenum was persistently irregular. The ileum was normal in position, freely movable, and contained the entire six-hour barium meal. At the twenty-four hour observation, the head of the barium column had reached the rectum. The cecum and the colon were normal. The appendix was not seen. A second roentgen-ray examination, one week later, gave the same findings.

Interpretation: The findings are those of either periduodenal adhesions or duodenal ulcer.

Clinical Pathologic Findings: The fasting stomach contents contained free hydrochloric acid, 15, and total acidity, 26. The guaiac test for occult blood was negative. After an Ewald test breakfast, free hydrochloric acid was 3 and total acidity 30.

The stools showed no occult blood. The Wassermann reaction in the blood serum was negative. The examinations of the blood and urine were negative.

Progress: The patient was in the hospital three days. During this period he was given the usual hospital soft diet and was free from all symptoms. After leaving the hospital he took a short vacation and then returned to work. In a letter, four months later, he stated that he had been free from all gastric symptoms since leaving the hospital.

That this case was one of duodenal ulcer cannot be denied, but the rapid recovery makes the correctness of that diagnosis problematic. This is emphasized by the failure to demonstrate at operation the presence of an ulcer in a case (Case 6, M. M. Mc., Med. No. 10448) reported elsewhere,² in which the clinical and

roentgenographic findings were almost identical with those in the case just described.

Such cases as these demand intensive study and long observation. The patient's reaction to medical treatment is a practical guide to follow. It has been thought that rest in bed, combined with dietary measures, is indicated in all cases in which there is considerable evidence of the presence of ulcer, such as existed in the case just reported. That this line of therapy will often produce quick results is shown by the results obtained in this case. However, there are patients on whom exclusion from business works a great hardship. Since the correctness of the diagnosis of ulcer is somewhat questionable in such cases, it seems justifiable to try ambulatory treatment provided the patient is kept under close observation. That such a course is not only justifiable, in selected cases, but that good results may be obtained is illustrated by Case 3:

CASE 3.—Diagnosis, *gastric ulcer*.—F. E. M., Med. No. 8260, white man, aged 21, student, admitted to the Peter Bent Brigham Hospital, May 6, 1918, and discharged May 25, 1918, whose family history was unimportant, since early childhood had lunched between meals because of hunger; also, the bowels had been more or less constipated, frequently requiring the employment of cathartics. During the twelfth year of age there had been frequent nausea and vomiting immediately after breakfast. The patient was slightly under weight.

The present illness had begun one year prior to admission to the hospital. The predominating symptom was dull pain, occurring from two to three hours after eating, accompanied by belching. The pain was always in the umbilical region. It was relieved by taking hot water, soda or food. There was no night pain. The pain persisted for three months and then disappeared. It reappeared four weeks prior to admission, and was of the same character as during the first attack.

Fig. 2 (E. W., O. P. D. 60463).—Normal outline of antrum disclosed when stomach was roentgenographed two weeks later.

The physical examination was essentially negative.

Roentgen Report: There was a moderate six-hour barium residue. There was a deep incisura in the prepyloric region. The incisura extended from the greater curvature, and divided the stomach almost into two cavities. The incisura was present throughout the fluoroscopic examination, and was seen on the plates. No irregularities in the stomach

2. Footnote 1, second reference.

outlines were made out. The duodenum could not be more than partially filled.

Interpretation: The findings are due to muscle spasm, and suggest gastric and duodenal ulcer.

Clinical Pathology: Twenty-six c.c. of fasting gastric contents were obtained, and they contained some food

Fig. 3 (Case 2).—Irregularity in outline of duodenum.

residue. The benzidin test for blood was negative. After an Ewald test breakfast, free hydrochloric acid was 3 and total acidity 24. The stools contained no occult blood. The usual examinations of the blood and urine were negative. The Wassermann test in the blood serum was negative.

Progress: After admission to the hospital, the patient was placed on a Sippy diet. Within seventeen days he was able to take a general diet without producing symptoms. The patient remained free from symptoms until April, 1919. At this time there appeared fairly severe epigastric pain every few days about two hours after meals. This condition continued for three months; then the epigastric pain became more or less constant. It remained of fairly severe intensity. This condition continued for two weeks. Then the patient went into the mountains on a vacation. There he tramped and ate liberally of a general diet. In spite of this he quickly became free from all symptoms and remained so until December, 1919. There then appeared either fairly sharp pain or marked discomfort in the epigastrium two hours after food. The pain or discomfort was relieved by soda or food. There was occasional vomiting and some belching of gas. Roentgenographic studies were made at this time. The stomach was found to be markedly atonic and contained a medium sized six-hour residue. Aside from these findings, the gastro-intestinal tract presented no abnormalities. It was now learned that the patient was subjected to much nervous strain and that he had been so prior to the onset of his trouble in 1918. He was told that, although he probably had a gastric ulcer, his symptoms might all be due to a neurosis. He was given treatment for gastric neurosis and was instructed to eat liberally of a bland diet for two weeks, after which time he was placed on a general diet. Within a few days after beginning treatment the patient became free from symptoms and remained so one month later.

Two other cases were observed in which the symptoms were those of peptic ulcer, but the roentgen-ray findings revealed only gastroparesis and atony. As in the case just reported, these two patients became free from symptoms under treatment for neurosis. Whether

or not these three cases were peptic ulcer could be determined only by operative methods. The subsequent courses of these cases and of Case 2 were like those of gastric neuroses. In all four cases the basis for a neurosis was present. On the other hand, the histories and roentgen-ray findings suggest the diagnosis of ulcer in two of the cases. The diagnosis in these cases must be left an open question in the absence of surgical exploration. But, as regards treatment, unless such cases quickly respond to other forms of therapy, it would be best to institute a medical regimen for peptic ulcer.

Roentgenographic findings may be very atypical and assist materially in the making of an incorrect diagnosis. Case 4 illustrates such an instance:

CASE 4.—Preoperative diagnosis, malignancy superimposed on an old ulcer; postoperative, gastric ulcer and benign pyloric stenosis.—J. C. B., Med. No. 11906, white man, aged 78, retired, admitted to the Peter Bent Brigham Hospital, Sept. 26, 1919, and transferred to the surgical service, October 14, entered the hospital complaining of "stomach trouble." The past medical history was unimportant. The symptoms consisted of anorexia, belching, and occasionally epigastric distress occurring from three to four hours after meals. The epigastric distress was temporarily relieved by soda or food. These symptoms had persisted with remissions and exacerbations for a period of six years. There had been no vomiting and no bloody or tarry stools. During the eight months preceding admission, distress from three to four hours after meals, flatulence and belching had been present continuously. There had been nausea occasionally, but no vomiting. During the latter three months of the present illness the patient had lost 35 pounds in weight.

Physical Examination: Other than the evidence of considerable loss in weight, the physical examination was essentially negative.

Roentgen Report 16090: Two fluoroscopic examinations were made. The stomach was dilated and atonic. Peristalsis on one examination was practically absent, while in the second it was vigorous and of the obstructive type. There was a constant filling defect in the region of the antrum, the margins of which appeared irregular in outline. The sphinc-

Fig. 4 (Case 4).—Appearance of stomach in a case that proved to be gastric ulcer and benign pyloric stenosis.

ter was not seen. Virtually the entire six-hour barium meal was in the stomach, and at the twenty-four observation the stomach was still outlined by barium.

Interpretation: The findings are those of a carcinoma involving the sphincter and causing pyloric obstruction.

Clinical Pathology: The fasting stomach contents contained remnants of food eaten fourteen hours previously.

Free hydrochloric acid was 10, and total acidity, 43. After an Ewald test breakfast the gastric contents contained, free hydrochloric acid, 40 and total acidity, 60. The benzidin test for occult blood was negative. Hemoglobin was 80 per cent. and the white cells 8,000 per cubic millimeter. The

Fig. 5 (J. S., Med. No. 12180).—Stomach in a case of duodenal ulcer. Arrow points to the duodenum which, together with the region of the pyloric sphincter, was pulled upward by a congenital band of adhesions.

Wassermann reaction in the blood serum was negative. The urine contained no pathologic elements.

Surgical Note: The preoperative diagnosis in this case was malignancy superimposed on an old ulcer. At operation the pylorus was found to be obstructed by a mass of scar tissue resulting from an old ulcer, and no evidences of malignancy were found.

In this case both clinical and roentgen-ray findings were distinctly those of carcinoma, yet the case was one of ulcer. This case illustrates that even the most typical roentgen-ray findings do not necessarily make a correct diagnosis. A correct preoperative diagnosis does not seem to have been possible. The roentgen-ray findings are portrayed in Figure 4.

In a case of pyloric ulcer (Case 2, J. S., Med. No. 12180), reported in a previous communication,² the pylorus and duodenum were adherent to the gallbladder by a congenital band of tissue. In the roentgenogram the deformity produced obscured that due to the ulcer and gave the appearance of the presence of an extra-gastric process, such as a tumor mass or adhesions. The condition found is presented in Figure 5. The symptoms present in the case were those typical of gallbladder disease, and the roentgen-ray findings seemed to confirm that diagnosis. In this case the roentgen-ray findings led away from, rather than toward, a correct diagnosis.

There is a gastric roentgen-ray finding of which three examples have been observed. The finding consists of an area on the lesser curvature over which peristaltic waves do not pass (Fig. 5). No irregularity in the outline of the stomach exists. Case 5 is an example of such a case:

CASE 5.—Diagnosis, *gastric ulcer*.—P. J. B., Med. No. 10993, white man, aged 46, watchman, a year and a half before, following a fall, had symptoms similar to the present attack,

during which 15 pounds in weight were lost. The present illness began seven weeks prior to admission to the Peter Bent Brigham Hospital, and again followed mild trauma. The symptoms had consisted of burning epigastric pain coming on about half an hour after meals. Occasionally nausea had been present, but no vomiting. The patient had lost 12 pounds in weight during the present illness. The physical examination was essentially negative except for some tenderness in the midepigastrium.

Roentgen Report 14697: The stomach was normal in position, tone and outline, and was freely movable. The peristalsis was irregular and sluggish; at times three waves were visible. There was a small six-hour residue. On the lesser curvature, proximal to the antrum, there was an area in which no peristalsis occurred, although peristaltic waves were seen to pass over the greater curvature opposite this area. The same phenomena were noted on a second examination one week later. There was no irregularity in outline of the stomach. A good sphincter and first portion of the duodenum was seen. At the six-hour observation, the ileum contained the entire barium meal. The cecum was not seen.

The laboratory findings in the blood, urine and stools were negative. The fasting gastric contents were 34 c.c. in amount and showed no free hydrochloric acid. The contents removed after a test breakfast contained: free hydrochloric acid, 30, and total acidity, 45. There was no occult blood. The Wassermann reaction in the blood serum was negative.

Progress: The patient was under observation in the hospital for two weeks. During this period he was on a general diet. He complained of more or less constant, dull epigastric pain.

Whether or not this case was one of ulcer was not determined, although the history and roentgen-ray findings make the accuracy of such a diagnosis probable. In a second case with identical roentgen-ray findings there was a history of dyspeptic symptoms, like those usual for a gastric neurosis of several years' duration. In a third case the symptoms were those of ulcer, and a gastric ulcer in the antral region was found at operation.

Cases such as the one reported above demand continued, careful study and observation. The character of the treatment will depend on the medical and financial conditions of each patient. Ambulatory treatment

Fig. 6 (Case 5).—Tracing of stomach made with the aid of the fluoroscope. Arrow points to the region on the lesser curvature over which no peristaltic waves were seen to pass.

may be tried first, as was done in Case 3. If this fails, then rest treatment and finally a medical regimen for ulcer should be instituted.

SUMMARY AND COMMENT

The findings in the cases reported demonstrate that:

1. Cases occur in which either the presence of an ulcer is not diagnosed, or in which the presence or

absence of an ulcer cannot be definitely determined except by exploratory operation.

2. It is necessary to interpret roentgen-ray findings in relation to the data obtained by careful and thorough clinical studies.

3. In certain cases roentgen-ray findings are more confusing than helpful in diagnosis.

It is obviously necessary for the internist to become familiar with roentgen-ray findings. But he can scarcely hope to become as adept as the expert roentgenographer, for roentgenology is specialized work requiring much knowledge, large experience and great skill on the part of the physician engaged in it. The best results are obtained by the proper cooperation of clinician and roentgenographer. The proper cooperation consists:

1. On the part of the roentgenographer, in the accurate description of roentgen-ray findings present, portrayal of the most probable conditions which they represent, and the exclusion of artefacts.

2. On the part of the clinician, in the integration of roentgen-ray findings into symptomatology and diagnosis.

THE USE OF BEEF-BONE SCREWS IN FRACTURES AND BONE TRANSPLANTATION

M. S. HENDERSON, M.D.
ROCHESTER, MINN.

In recent years, bone grafting has become established in surgical practice as firmly as the more simple operation of skin grafting, and, as in the latter, it has been found that the autogenous graft is the best. Practically all failures can definitely be attributed to technical errors, such as too small a graft, infection, inadequate fixed bony approximation of the graft to fragments, and poor postoperative fixation of the part. I have found beef-bone screws to be a great aid in attaining this fixed approximation of the graft to the bone, and I believe that they would be employed more if their uses and methods of preparation were more generally known. I am well aware of the fact that a few surgeons have used them, but I present this article on their preparation and use believing that it may be of interest to others.

There can be no doubt that, from a purely theoretical point of view, screws made from the bone of the patient, such as the bone pegs advocated by Albee, would be better than beef-bone screws. The theory when put into practice, however, has so many objections, such as the difficulty of making the screws or pegs properly, and the extra amount of bone used, that I have come to the conclusion that the beef-bone screws are to be preferred. The question of whether the beef bone is suitable for a graft does not enter into this discussion, for all that is demanded of the screws is that they provide fixation of the autogenous graft to the fragments. They are usually absorbed completely within from six months to a year.

We know that the bone transplant must be held firmly in position and have broad contact with the bone to which it is to be grafted. While in theory an inlay graft is best and occasionally it is possible to obtain a perfectly fitting inlay by the use of the double bladed circular saws, in actual practice this is not easy. If the blades of the twin saw are out of line there

will be a considerable discrepancy in the size of the graft and the slot. It is necessary to employ some means of securing the graft to prevent it from moving. Kangaroo tendon or catgut sutures thrown about the fragments and the graft are not satisfactory. Beef-bone screws properly placed are well-nigh ideal for the purpose.

PREPARATION OF SCREWS

Fresh beef bone is obtained usually from the tibia, the joint ends are sawed off, and the shaft is boiled for one and one-half hours to remove the tissue and the marrow. The shaft is sawed into pieces $3\frac{3}{4}$, $2\frac{3}{8}$ and $1\frac{1}{4}$ inches long for the large, medium and small size of screws, respectively. The medium sized screw is of aid in many situations, and many more of these are used than of either the large or the small screws. The sizes used by us are standard, and in mechanical terms the large screws are known as $\frac{5}{16}$ by 18, the medium size as 10 by 24, and the small as 6 by 32. The lengths

Fig. 1.—Piece of beef-bone with strips, blanks and screws: A, medium sized screw, 10 by 24; B, large sized screw, $\frac{5}{16}$ by 18.

adopted are arbitrary and may be varied to suit the needs of the case. The pieces are sawed lengthwise into strips; their width varies according to the diameter of the screw to be made. The strips are roughly sized in the vise by filing, and are then turned to the proper size, pointed, and the head rounded in the lathe. These finished blanks are placed, for one-half hour, in petrolatum brought to the melting point in a double boiler, in order to replace to some extent the natural oils removed by the boiling. This renders the bone a little less brittle and less likely to crumble when being threaded. The heat must not be extreme or the bone will be overheated and rendered almost chalky.

The blanks are placed in the lathe and threaded by using a standard machine screw die. Petrolatum is freely used on the die while the threads are being cut. The large blank is threaded with a standard $\frac{5}{16}$ inch by 18 die. The head is $\frac{5}{16}$ inch long and is flattened on two sides to $\frac{1}{4}$ inch in thickness to fit a special wrench. The large screw when finished is ordinarily $3\frac{1}{2}$ inches long, but this may be varied. The medium sized blank is finished into a screw $\frac{19}{100}$ inch in diameter and $2\frac{1}{4}$ inches in length (Fig. 1). A little more care is necessary in putting the threads on this size than on the large screw, and

we have found it necessary to step down the threads by using three dies: 12 by 24, 11 by 24, and 10 by 24. The small blank is for a screw $\frac{1}{4}$ inch in diameter and $1\frac{1}{8}$ inches long. It is necessary to step down the threads for this screw as follows: 8 by 32, 7 by 32, to 6 by 32. The heads of the two smaller screws are $\frac{1}{4}$ inch long and $\frac{1}{4}$ inch in diameter to allow for hexagonal shaping to a $\frac{3}{16}$ inch standard. These fit a specially made socket wrench fitted to the end of a small brace. When the screws are received from the machine shop they are thoroughly scrubbed with soap and water and boiled in water for thirty minutes. They are then kept in the instrument case and boiled as required, just as any instrument is boiled. The screws are cheap, easily made and well tolerated by bone. The one objection to them is that they are brittle and will not withstand any great amount of stress, particularly if there is any torsion with the strain. For his interest and skill in the actual manufacture of the screws we are indebted to Mr. George Little, chief of the instrument shop of the Mayo Clinic.

SURGICAL USES

Even though the beef-bone screws are well made, they cannot be successfully used unless there are at hand the proper instruments for placing them. Above all, it must be remembered that they withstand very little twisting force, and if they bind when being screwed in, they will break. For the large size, $\frac{5}{16}$ by 18, a special socket wrench is used. I have used the large screws only in situations such as the head of the femur or the condyle of the femur. If not passed through any cortical bone, they are of sufficient

Fig. 2.—Instruments necessary for the placing of beef-bone screws: A, No. 17 twist drill; B, straight handled 10 by 24 tap; C, offset handle 10 by 24 tap; D, offset handle wrench with hexagonal headed beef-bone screw in socket; E, straight handle wrench.

fully done by hand. Handles of different styles for the wrench and taps will be found convenient for the different situations (Fig. 2 B and C). If the subcutaneous structures are scanty, the heads of the bone

screws may be removed either by bone-biting forceps or a Gigli saw.

In recent spiral or oblique fractures of the long bones, recent fractures of the neck of the femur, of the olecranon process, and in certain fractures of the

Fig. 3.—Curved tibial bone graft (a) held securely in place by the aid of two beef-bone screws placed through the graft and spinous processes; b, transverse section showing the relative positions of the graft, spinous process and beef-bone screw.

patella, the screws are an excellent means of obtaining coaptation of the fragments. They are a splendid means of fastening the bone graft to the spinous processes, as is necessary in the operation advanced by Albee for tuberculosis of the spine, and are the only means known to me whereby proper bony approximation can be assured (Fig. 3). They are not so ideal in delayed union or for ununited fractures. It has been my experience that in fractures of these two groups, it is best to accept no compromise but to employ a large graft so that when the operation is completed there is from 20 to 25 per cent. more bone in the fractured region than is normal (Fig. 4). When we are dealing with a case of long standing nonunion of the humerus or of the bones of the forearm, the bones are often osteoporotic and smaller than normal. In such cases every surgeon of experience has seen his inlay or intramedullary grafts thin out and finally break at the line of fracture. The absorption of the graft takes place so rapidly, or perhaps it would be better to say that the deposition of new bone is carried on so slowly, that the graft is partially absorbed and cracks on slight stress, and a technically well performed operation in a properly selected case is discredited. In such a predicament the surgeon should not be dismayed and give up all hope of obtaining union, but he should at once see that the part is thoroughly immobilized for at least two months more. In the majority of cases, and particularly if the transplant has been of good size, union will occur. I believe that

the excess of bone elements brought to the devitalized area is an important causative factor in bringing about union, and this is my reason for so strongly emphasizing the large graft. If the roentgen ray discloses very marked osteoporosis of the fragments, exercises should be instituted prior to operation, regardless of the fracture, because it is only by this means that the osteoporosis will be overcome. Many failures to obtain bony union are due to operating on bones that are far below par in bone salts and bone forming elements. Obviously, the simplest way to prevent a fracture of the transplant is to place a very large graft, and by this I mean large in diameter as well as in length (Fig. 4 b). The discredit of the bone graft found in some of the recent writings, particularly from abroad, is more than likely due to the authors' experiences with fracturing of the grafts, the cause of which is probably the use of too small transplants.

The technic of the inlay graft will not permit the placing of a very broad piece in the fragments (Fig. 4 c). On account of failure and accidents with the ordinary intramedullary and inlay grafts, and the belief that it is most important to place more bone in the fractured area than is normally there, it has been my custom for some time to proceed as follows: The bone ends are carefully freshened so that as broad an area of their surface as possible will be in firm contact. The medullary cavity in each fragment should be opened. From one fifth to one fourth of the entire thickness of the bone from each fragment on one side is removed for a goodly distance above and below the fracture. This should not remove the entire cortical wall. The graft, which is a piece of healthy bone from the tibia or the entire thickness of the fibula, flattened on one side, is greater in thickness than the amount of bone removed from the fragments, and is placed against their freshened surfaces, the ends of which are in firm apposition and the medullary cavities in line. It is held in place by two or more beef-bone screws through the graft and through the remains of the proximal cortex and the opposite cortex of each fragment (Figs. 5 and 6).

SUMMARY

1. Beef-bone screws are a great aid in securing firm fixation of the bone graft to the fragments in frac-

Fig. 4.—a, transverse section of bone; b, large bone graft in apposition to fragment from which part of cortex has been lifted to permit broad contact; graft held in place by beef-bone screws through the opposite cortex; c, inlay graft; beef-bone screw placed through graft and the opposite cortex.

tures, and of the graft to the spinous processes in the operation for fixation of the spine.

2. They are well tolerated by the bone and are gradually but completely absorbed.

3. Bone screws have not the strength of metal and must not be expected to stand great stress. Careful provision must be made for postoperative fixation of the extremity.

4. Drills, taps and wrenches of the proper size are essential for the placing of beef-bone screws.

5. The bone graft as commonly used in the intramedullary and inlay methods is too small. Fracture of

the graft rarely, if ever, occurs if the graft is large enough so that when the operation is completed there is from 20 to 25 per cent. more bone in the fracture area than there is normally.

Liquid Disinfectants.—Liquid disinfectants may be substances either in solution or suspension. There are certain principles to be observed in the use of liquid disinfectants. A hot liquid disinfectant acts much more powerfully and quickly than a cold one. A disinfectant that is efficient at a certain percentage must be in that percentage in the mixture; for example, a disinfectant that will effectively disinfect at 2 per cent. strength must be present in a 2 per cent. strength in the resulting mixture. An emulsion is, as a rule, more germicidal than a solution because the germs come in contact with the crude drug, but a solution has more penetrative power than an emulsion. Each type of disinfectant has its own time necessary for efficient disinfection, e. g., a disinfectant that requires one-half hour to disinfect will not disinfect in fifteen minutes. The following disinfecting solutions are most commonly used: mercuric chlorid solution, 1:100 dilution or 1:1,000 solution for one-half hour (can not be used in albuminous medium or on metals, as it corrodes them); phenol, 5 per cent. solution for one-half hour; cresol, 2 per cent. emulsion for one-half hour; liquor formaldehydi, 10 per cent. solution for one-half hour; chlorinated lime, 5 per cent. solution for one hour (for disinfection of water, 1:150,000 solution for one-half hour is effective).—*U. S. Naval Medical Bulletin*, January, 1920.

BOTULISM

PRELIMINARY REPORT OF A STUDY OF THE ANTI-
TOXIN OF *BACILLUS BOTULINUS**

ERNEST C. DICKSON, M.D.

AND

BEATRICE M. HOWITT

SAN FRANCISCO

The experiments recorded in this report were performed during the year 1917-1918, but on account of war conditions it was not possible to carry them further or to record them at that time. We had planned to delay publication until further experimental data could be obtained concerning a number of points that are obviously unsettled; but on account of the widespread interest that has recently been aroused in the subject of botulism, and the expression of various theories and speculations concerning the value of botulinus antitoxin as a therapeutic agent, we are offering this as a preliminary report with the hope that it may draw attention to certain facts that have been established.

THE PRODUCTION OF ANTITOXIN

Kempner,¹ in 1897, for the first time demonstrated that susceptible animals may be immunized to the toxin of *B. botulinus* (he used the Van Ermengem strain), and that a potent antitoxin may be produced. He was unsuccessful in his attempt to immunize the smaller laboratory animals, but succeeded in immunizing goats and in obtaining a potent antitoxin, 1 c.c. of which would protect against 100,000 minimal lethal doses for guinea-pigs.

Forssman and Lundstrom² succeeded in immunizing rabbits and guinea-pigs by using toxin that had been attenuated by heating for the first injection. They also immunized goats, and found that they obtained more rapid antitoxin formation if they injected the toxin subcutaneously than when they employed intravenous injections, and if they gave comparatively small amounts of toxin at comparatively longer intervals than were used by Kempner.

Wassermann³ and Leuchs⁴ were both successful in immunizing horses, and Leuchs recorded a comparative study of the toxin-antitoxin relationships of the Van Ermengem strain and the Darmstadt strain of *B. botulinus* in which he showed that the two strains were distinct in that the toxin of one was not affected by the specific antitoxin of the other, and vice versa. Leuchs was therefore the first to recognize that there are at least two types of *B. botulinus*, and that if immune serum is to be used therapeutically it should be a polyvalent serum.

In this country several investigators have prepared botulinus antitoxin for experimental purposes, but as yet none is available for commercial distribution. Graham, Brueckner and Pontius⁵ prepared antitoxin

by injecting sheep, goats and cattle with toxin of the Niven strain (Strain VI of our series) and with toxin from strains which they isolated in outbreaks of forage poisoning. Buckley,⁶ at the U. S. Department of Agriculture, has prepared an antitoxin for the strain which was isolated by Thom, Edmonson and Giltner from asparagus which caused the poisoning at Boise, Idaho. Hart,⁷ at the University of California Department of Agriculture, has immunized horses to strains that were obtained from our laboratory. Meyer, Hurwitz and Taussig⁸ successfully immunized dogs against the toxin of our Strain III, and Mrs. Burke⁹ reports the immunization of rabbits.

We obtained the antitoxin used in our experiments by inoculating Goats 1, 2 and 3 with Strains III, IV and VI, respectively, of our strains of *B. botulinus*

TABLE 1.—IMPORTANT DATA CONCERNING THE HISTORY OF
THE STRAINS OF *B. BOTULINUS* STUDIED IN
THIS INVESTIGATION

Strain	Date	Location	Persons		Poisoned		Cause of Poisoning	B. Botulinus Recovered From
			Ill	Died	Fowl	Animals		
III	1915	San Jose, Calif.	1	1	8	Home-canned string beans	Contents of chicken crop
IV	1914	Hillshoro, Ore.	1	1	50	Home-canned corn	Contents of chicken gizzard
VI	1915	Albany, N. Y.	?	?	Cheese	Cheese (the Niven strain)
VII	1917	Seattle	3	3	20*	Home-canned asparagus	Contents of chicken crop
VIII	1918	Berkeley, Calif.	12	Home-canned string beans	Unopened jar of same lot of beans

* Approximately.

over a period of several months. We were unable to follow out any previously determined plan for inoculating, as the goats reacted so differently to inoculation that we were forced to regulate the dosage and interval by the condition of each animal at the time. We did not obtain as highly potent antitoxins as Kempner or Forssman and Lundstrom report, although they were of sufficient potency for experimental purposes.

TABLE 2.—PRODUCTION OF SPECIFIC ANTITOXIN FOR
TOXIN OF STRAIN III

Guinea-Pig	Weight, Gm.	Toxin III, C.c.	Antitoxin III, C.c.	Results

The potency of our three antitoxins, and the fact that they will neutralize the effect of the toxin when multiple proportions of the test dose of toxin and of antitoxin equivalent are mixed in vitro and injected into animals, are shown in Tables 2 to 7, inclusive. In all our experiments, unless it is otherwise stated, the toxins and antitoxins were mixed in vitro before

against one test dose of its homologous toxin. Our figures are only approximate, however, as it was impossible to obtain a sufficient number of guinea-pigs of the same weight to standardize our injections accurately. On this account we adopted the rule of using our heaviest animal for the toxin control, or, when the variation in weight was too great, of using two or more animals of different weights as toxin controls. In subsequent experiments we hope to establish more accurately standardized results.

EXPERIMENTS TO TEST THE EFFECT OF ANTITOXINS III, IV AND VI ON THE TOXINS OF OTHER AVAILABLE STRAINS OF *B. BOTULINUS*.

In our experiments we have investigated the toxins of seven strains of *B. botulinus*, six of them strains that were recovered in our laboratory from various home-canned vegetables and fruits that had caused outbreaks of food poisoning on the Pacific Coast, and one that was recovered by Niven from cheese in New York State. We did not test Strains I, II and V of our series because of the very low virulence of their toxins. The histories of the strains investigated are abstracted in Table 1.

(a) Experiments to test the action of Antitoxin III against the toxins of Strains IV, VI, VII, VIII, IX and X, respectively (Table 8): The experiments show that Antitoxin III has a protective action against

63	325	X	0.75	1	Died in approx. 18 hours

the toxins of Strains IV, VII and IX as well as against its own Toxin III. Although the tables have been abbreviated, sufficient data are given to show that 1 c.c. of Serum III protects against approximately 5,000 test doses of Toxin IV, an even higher degree of protection than was obtained in our tests of Antitoxin III against Toxin III (Table 2). Quantitative tests against Strains VII and IX are not given.

It is also shown that Antitoxin III has no appreciable effect in protecting against the action of Toxins VI, VIII and X, although an antitoxin equivalent of 3,000 test doses was given in each case. This has been confirmed by many trials.

(b) Experiments to test the action of Antitoxin IV against the toxins of Strains III, VI, VII, VIII, IX and X, respectively (Table 9): The experiments show that Antitoxin IV protects against the same toxins as Antitoxin III, namely, against III, VII and IX as well as against its own toxin. Like Antitoxin

III it does not show any appreciable protective action against Toxins VI, VIII and X.

(c) Experiments to test the action of Antitoxin VI against the toxins of Strains III, IV, VII, VIII, IX and X, respectively (Table 10): The experiments show that Antitoxin VI has no appreciable protective action against the toxins that are counteracted by Antitoxins III and IV, namely, III, IV, VII and IX, but that it does protect against Toxins VIII and X, which are not affected by Antitoxins III and IV.

75	325	X	0.75	1	Survived

From the foregoing experiments it is clear that there are in this country at least two types of *B. botulinus* which can be easily differentiated by toxin-antitoxin tests. The seven strains which we investigated fall into two homologous series of four and three, respectively, and have been described as Types A and B. So far as our investigations have gone, there appears to be very little if any cross protection afforded by the antitoxin of either type for the toxin of the other, a fact that will be referred to later in discussing the therapeutic value of botulinus antitoxin.

EXPERIMENTS TO TEST THE EFFECT OF THE ADMINISTRATION OF SPECIFIC ANTITOXIN AT VARYING INTERVALS AFTER THE INJECTION OF TOXIN

In the following experiments the toxin and antitoxin of Strain III were employed. The amount of antitoxin is indicated in every case in terms of the anti-

TABLE 11.—RELATIVE AMOUNTS OF ANTITOXIN NECESSARY TO PROTECT AGAINST ONE TEST DOSE OF TOXIN, WHEN ANTITOXIN AND TOXIN ARE MIXED IN VITRO, AND ARE INJECTED SEPARATELY

Guinea-Pig	Weight, Gm.	Toxin III, C.e.	Antitoxin III, C.e.	Method of Administration	Results
76	300	0.001	(Toxin control)	Died in approx. 36 hours
77	250	0.001	0.0005	Mixed in vitro	Survived
78	250	0.001	0.0005	Separately	Died in approx. 60 hours
79	250	0.001	0.001	Separately	Died in approx. 60 hours
80	275	0.001	0.002	Separately	Ill but recovered

toxin equivalent of one test dose of toxin when mixed in vitro. The antitoxic serum of Strain III was such that 1 c.c. gave complete protection against 3,000 test doses.

(a) Experiments to show the relative proportions of antitoxin necessary to protect against one test dose of toxin when the toxin and antitoxin are mixed in vitro before injection, and when the toxin and antitoxin are given simultaneously but injected separately (Table 11): It was found that it requires at least four times as much antitoxin to neutralize one test dose of toxin in vivo as is necessary when the two are

mixed in vitro. In all our experiments, therefore, in which we have attempted to determine the interval after the injection of toxin during which the administration of antitoxin may be of value, we have employed at least five times the antitoxin equivalent of one test dose of toxin when the two are mixed in vitro.

(b) Experiments to test the value of injecting antitoxin at varying intervals after the administration of toxin: 1. In the first series of experiments, slightly more than one test dose of toxin was injected subcutaneously (the animals died in from thirty-three to forty hours after the injection, whereas if one test dose had been given they should have survived for forty-eight hours); and at intervals of six, twelve, eighteen and twenty-four hours thereafter, varying amounts of antitoxin, from 5 to 250 antitoxin equivalents, were injected, also subcutaneously. Guinea-pigs were used for the experiments, and a toxin control animal was injected for each group (Table 12).

TABLE 12.—EFFECT OF INJECTING VARYING AMOUNTS OF ANTITOXIN AT VARYING INTERVALS AFTER ADMINISTRATION OF SLIGHTLY MORE THAN ONE TEST DOSE OF TOXIN

99	200	0.0005	0.025	50	24 hours	Died in approx. 36 hours
100	200	0.0005	0.125	250	24 hours	Died in approx. 36 hours

* The animals were ill but recovered.

The experiments indicate that when slightly more than one test dose of toxin is injected, the lives of the animals may be saved if the antitoxin is given within eighteen hours after the toxin, although it does not prevent the onset of symptoms even when given twelve hours after. They also indicate that an excess of antitoxin affords no greater protection than smaller amounts, provided the smaller amount is sufficient to neutralize the amount of toxin administered.

2. In a second experiment, one test dose of toxin was injected subcutaneously (the control animal died in forty-eight hours), and an excess of antitoxin was injected at intervals of six, twelve, eighteen and twenty-four hours thereafter (Table 13). The animals all survived, showing that when a smaller amount of toxin is injected, the length of time during which the antitoxin may exert its influence is lengthened, and that, under such circumstances, if given within

twenty-four hours after the toxin, it may afford full protection.

3. A third experiment was performed in which rabbits were fed sufficient toxin to kill the control in approximately forty-five hours, and at varying intervals thereafter an excess of antitoxin was injected subcutaneously (Table 14).

The animals all survived, showing that when the toxin is administered by feeding as well as when it is injected subcutaneously, the administration of antitoxin may be of value if given within twenty-four hours after approximately one test dose (by mouth) of toxin.

THE THERAPEUTIC VALUE OF BOTULINUS ANTITOXIN

So far as we have been able to learn, there is no great amount of published data concerning therapeutic or prophylactic use of botulinus antitoxin. In this country, until very recently, the only available supplies of specific antitoxin have been at the Department of Animal Husbandry, University of Illinois, and at our own laboratory; but as stated earlier in this report, several investigators are now preparing antitoxin for experimental purposes. An attempt has been made in several outbreaks to combat the intoxication by administering antibotulinus serum, but without any very satisfactory results. Feb. 2, 1918, we gave 85 c.c. of immune goat serum¹⁰ (Mixture of A and B) by subcutaneous injection to each of two patients at Madera, Calif.¹¹ Both patients recovered; but as the antitoxin

was given very late, in fact, after all the more seriously poisoned patients had succumbed, there is no definite evidence that the course of the illness was favorably influenced by the antitoxin, although it was later shown that the toxin of the strain recovered from the food was Type A.

McCaskey¹² has reported the administration of small doses of antitoxin to three patients who were

poisoned by home-canned string beans at Decatur, Ind. The antitoxin was given in small doses, from 5 to 10 c.c. One of the patients died and two recovered, and McCaskey believes that the serum was of some aid. Graham's antitoxin, which was Type B, was used in this outbreak, and the organism that was later recovered has proved to be of the same type.

At Detroit, in October, 1919, Jennings, Haass and Jennings¹³ administered antitoxin which was obtained from Graham at the University of Illinois. They injected 42 c.c. of serum intravenously in one case

* Human beings were fatally poisoned.

without any apparent effect, and 20 c.c. in two injections to another patient, who recovered. They state that in the latter case the illness was so mild that they could "not state that the serum had any influence on her recovery."

There are newspaper reports that the Graham antitoxin has been used again in a recent outbreak of botulism in New York; but so far as we could learn, these have been all the instances recorded in the medical literature in this country.

It has been stated that there are two types of *B. botulinus* in this country, Types A and B, and that the antitoxin of one type has no apparent effect on the toxin of the other. We have had an opportunity of testing a sample of the Graham antitoxin and found it to correspond to our Type B, and Mrs. Burke⁹ has shown that eight of Graham's strains of *B. botulinus* belong to Type B. It is probable, therefore, that, except in our own cases, only Type B serum has been administered in all of the cases in this country, a point that must be remembered before one arrives at any definite conclusion concerning the value of botulinus antitoxin as a therapeutic agent.

In Table 15 we have tabulated all the strains of *B. botulinus* which we have been able to obtain from outbreaks in which food prepared for human consumption was the carrier of the toxin. A survey will show that of all the outbreaks in which the serum has been used, with the exception of that at Decatur, Ind., the toxin was produced by a strain of Type A, and consequently when Type B serum was used it could not

10. One c.c. of antitoxin was equivalent to approximately 3,000 minimal lethal doses for a guinea-pig.

be expected to give any satisfactory results. As it is impossible, except by laboratory experiments which consume valuable time, to know what type of toxin is responsible for the poisoning in a given outbreak, it will obviously be necessary to have a polyvalent antitoxin if satisfactory results are to be obtained.

It is our opinion that large doses of antitoxin should be given since the amount of toxin ingested is unknown, and that it should be given intravenously. In case we have an opportunity of observing any more cases we propose to follow the following plan: The usual precautions for the administration of horse serum will be observed, and the patient will be tested by intracutaneous injection for evidence of hypersensitiveness. When no hypersensitiveness is shown, the serum will be given at once and will be injected into the veins very slowly, not more than 1 c.c. a minute, until the full amount is given. When hypersensitiveness is shown, preliminary subcutaneous, intramuscular and intravenous injections of 1 c.c. at one hour intervals will be given, and one hour after the last injection the full amount will be injected intravenously at the rate of not more than 1 c.c. a minute.

CONCLUSIONS.

1. A true antitoxin may be prepared for the toxin of *Bacillus botulinus*.
2. There are at least two types of *B. botulinus*, which are distinct so far as their toxin-antitoxin relationships are concerned.
3. Experiments show that in the laboratory the antitoxin may protect against the action of the toxin for at least twenty-four hours after the administration of one test dose of toxin, but that the effectiveness is, to a certain extent at least, dependent on the amount of toxin injected.
4. For therapeutic administration a polyvalent antitoxin should be employed, and it should be given in large amounts and intravenously.

DIVERTICULITIS

REPORT OF A CASE WITH ACUTE PERFORATION

CLARENCE F. BALL, M.D.

RUTLAND, VT.

Diverticula of a viscus may be either congenital or acquired, and they occur rather more frequently in the intestinal tract than in any other of the hollow viscera. A diverticulum is in reality a hernia outward through the wall of the viscus, carrying before it the mucous, atrophied muscularis and serous layers; or, as in some instances, only the mucous coat extrudes through the muscularis, carrying with it the serosa. The larger number, undoubtedly, are acquired, and it has been suggested that they occur more frequently where the artery penetrates the wall. They are complete or incomplete, depending on the extent of the evagination. When acquired, they occur almost invariably past middle life. Diverticula of various portions of the digestive tract are occasionally discovered in the course of an intensive roentgenologic study of the digestive tract. Multiple diverticula not giving rise to a definite set of symptoms constitute a condition termed diverticulosis, in contrast to diverticulitis, which should apply only to diverticula that do give rise to symptoms.

Diverticula of the digestive tract are found to involve the colon more frequently than any other portion. The sigmoid is the most common seat of location, and the transverse colon, cecum and rectum, in the order named, are the next most common locations. Diverticula of other portions are the exception. Diverticula in diverticulosis fill with and empty of bowel content without symptoms. The frequency with which roentgenologic studies are made of the gastro-intestinal tract for gastric disturbances demonstrates that diverticulosis is not uncommon.

A roentgenologic study is essential in making a differentiation between nonsurgical diverticulosis and surgical diverticulitis cases. True or complete diverticula, having a rather constricted opening, ultimately give rise to a set of symptoms either acute, subacute or chronic. False or incomplete diverticula rarely cause symptoms. Diverticula with retained fecal matter are potential sources of danger, the same as an appendix containing a fecal concretion. Sooner or later an acute inflammatory process takes place with rupture, if surgical interference is not resorted to early. In acute diverticulitis, operative interference is essentially the same as for acute appendicitis—that is, the diverticulum should be isolated from within the folds of the inflamed and indurated peritoneal tissues and clamped off close to the intestine, tied, and phenolated.

Some acute and almost all subacute and chronic manifestations, from the literature on the subject, seem clinically to be confused more with malignant processes than with any other single condition. In fact, one author gives statistics wherein the larger portion of the cases reported were considered, prior to operation, in one sense or another as probably malignant, the true nature of the condition not being determined until after resection of the mass involved. Since a diverticulum seldom occurs alone, except in the esophageal type, one should always, when operating on other portions of the digestive tract, make search for other diverticula which might possibly contain fecal concretions without inflammatory manifestations.

Small diverticula containing fecal concretions may readily be considered, when found adjacent, as enlarged glands incident to an acute or malignant process. These should be incised to determine their true nature and not left as a potential source of future trouble. Uncertain peritoneal fat accumulations also should be investigated by incision. Since diverticulitis may be confused with malignant processes, one must not consider, even in acute cases, any apparent associated glandular enlargements as such without incising them to determine their true nature. Further, if one was uncertain relative to a mass with supposed glandular enlargements, one could make the differential diagnosis by opening it. The presence of a fecal calculus would be practical evidence that the associated process was due to an advanced diverticulitis instead of to a malignancy.

REPORT OF CASE

History.—R. A. W., man, aged 58, who was 5 feet 10 inches in height and weighed 180 pounds, erect and well proportioned, with good habits and negative early history, had worked hard in the packing department of a scale works up to the day before the operation. The patient's recent history had been negative except for the presence of an "uncomfortable feeling" in the left lower abdomen for some months previous,

with an occasional sharp pain lasting a few minutes. There was no diarrhea. The patient was slightly constipated at times, which condition had no relation to his abdominal discomfort. No blood had been noted in the stool at any time. He had a mild attack of "bowel trouble" during the influenza epidemic in September, 1918, at which time he was away from work about a week. I attended him then, but his true condition was not even suspected, much less recognized. A mild cathartic, rest in bed, and restricted diet relieved the entire situation. He had no other attack until the present one, May 14 and 15, 1919. I saw the patient early on the morning of the 15th. He had had a bad night and seemed desperately ill, with pain and tenderness in the left lower abdomen. On manual examination the entire abdomen was rigid, but more so on the left side. The legs were drawn up and respiration was short and grunting. The patient could extend his legs, but complained on straightening out his left leg. There was faulty left leg flexion on the abdomen with manual pressure over the tender area. He had a temperature of 100.4, pulse 88, respiration from 22 to 24. A tentative diagnosis of an acute pathologic condition of the structures in the left side of the abdomen was made, and the patient was taken to the hospital. Morphine sulphate, one-fourth grain, was administered hypodermically before he left home, and blood and urine examinations were made immediately on his arrival. The urine was negative except for a few hyaline and granular casts. The heart and lungs also were negative. Blood counts revealed 15,000 leukocytes per cubic millimeter, with 83 per cent. polymorphonuclears, which indicated the necessity of immediate operation.

Operative Findings.—At noon, the abdomen was opened in the median line. The bowels were distended with gas and the peritoneum was markedly congested, especially to the left of the incision. The omentum was adherent over a mass in the left flank. There was a moderate increase of fluid. The mass was found adherent to the sigmoid, a part of which it seemed to be when the hand was first put into the abdomen. A cleavage line soon freed the sigmoid of suspicion as to a possible perforating malignant process. As the mass in the hand was freed from the sigmoid and brought up into the wound, it had more the appearance of a malignant process with perforation of the colon into the indurated mass surrounding it than of an acute process. An adjacent *enlarged gland* rather added to this suspicion when I first inspected the mass.

Palpation of the colon from the cecum to the location of the mass showed it to be located in the ascending loop of the transverse colon opposite to and adherent to the sigmoid colon, from which it had just been freed. As the result of a further attempt to determine the exact nature of the lesion, another cleavage line allowed of a partial separation of the mass from the wall of the intestine down to what appeared to be extruded intestinal wall tissue. It was at this time that the actual pathologic condition first dawned on me. Finger dissection, carried around the mass, freed it from the intestinal wall except for rather a short pedicle. The pedicle was double clamped and was cut between the clamps, freeing the indurated mass from the bowel. After removal it was immediately opened and found to contain a fecal concretion, the size of a small filbert, protruding through the ruptured end of the diverticulum. The stump of the pedicle was then tied and phenolated. This completed, the adjacent supposed *enlarged gland*, surrounded by a considerable amount of fat, was investigated by incision through its uninflamed covering. It also was found to contain a fecal concretion. The entire colon was then investigated and found to contain numerous filbert-sized fat accumulations along the surface. These were suspected of being other diverticula, not obstructed. This was later demonstrated to be the case, as shown by a roentgenogram that was taken after the patient had recovered and resumed his former duties. Operative recovery was complicated by superficial wound sepsis, but otherwise recovery was excellent. The postoperative history to date has been negative. The patient considers himself "better than for years."

ROENTGEN-RAY STUDY OF THE GREAT VESSELS

CHARLES L. MARTIN, E.E., M.D.

House Physician, Roentgen-Ray Department, Massachusetts General Hospital
BOSTON

Roentgen-ray investigation of the living heart was begun more than a decade ago. Groedel,¹ Dietlen,² Moritz,³ Claytor,⁴ Merrill,⁴ Veith,⁵ Bordet⁶ and Vaquez⁶ were active in forwarding the work. The late Dr. Walter James Dodd took up the subject at the Massachusetts General Hospital some ten years ago, and established a routine method of cardiac examination. A few years later Dr. George W. Holmes⁷ added his efforts to those of Dr. Dodd, and has continued the work since the untimely death of the latter. A careful comparison of the percussion outlines with the roentgenographic outlines of the heart was rendered possible through the cooperation of Dr. George C. Shattuck of the medical service of the Massachusetts General Hospital. His findings and an excellent review of the literature were published⁸ in 1916. The work of these investigators was for the most part directed toward the study of the heart itself, and the great vessels were considered of secondary rather than of primary importance.

The accurate percussion of supracardiac dulness is often extremely difficult, especially in the presence of obesity. Even when the width of this dulness can be determined with some certainty and the clinician is sure that it is increased, he is sometimes at a loss to interpret the finding. This is due to the comparatively large number of pathologic conditions that may occur in the upper mediastinum. These conditions may be roughly divided into (1) those not involving the great vessels, and (2) those caused by changes in the great vessels.

The first classification includes such conditions as substernal thyroid, enlarged thymus, mediastinal tumor, and enlarged mediastinal glands. The value of the roentgen ray in establishing these diagnoses is well recognized.

It is my object here to describe the roentgen-ray findings in a series of cases falling under the second classification. Six causes of increase in the width of the shadow of the great vessels have been observed, namely, chronic lesions of the mitral valve, causing a dilated pulmonary artery and left auricle; arteriosclerosis; syphilitic aortitis, which may or may not have reached the stage of aneurysm; long continued hypertension; a high diaphragm; and a dilated pulmonary artery, such as occurs with some congenital hearts.

All of the drawings used to illustrate these conditions are traced from "7-foot-plates" made by the teleroentgenographic method. The patient sits erect, with the anterior surface of the chest placed against a cassette containing a plate and an intensifying screen. The tube stand is placed behind the patient so that the focal spot of the tube is at a distance of 7 feet from the cassette and centered a short distance above a point

midway between the angles of the scapulae. The exposure is made during normal respiration in order that there may be no errors due to abnormal positions of the diaphragm. It is important that the patient be placed squarely against the cassette, because slight rotation will cause distortion of the cardiac shadow. Exposures of from fifteen to twenty seconds are used.

A silhouette of the heart and great vessels is obtained which is practically free from distortion and may be used for mensuration. In order to emphasize the shape of the silhouettes, outline drawings have been traced from the plates. These drawings represent the borders of the heart and great vessels, the approximate positions of the diaphragmatic domes, and the inner borders of the thoracic cavity. The histories and clinical findings are taken from the clinical records of the Massachusetts General Hospital.

Although this paper deals for the most part with the roentgenographic appearance of the heart, the reader is not to infer that fluoroscopic examinations are not of considerable value. A fluoroscopic tracing of the outline of the heart and great vessels made while the patient faces the observer is a routine procedure used by the roentgen-ray department at the Massachusetts General Hospital. A second tracing is made of the aortic arch with the patient rotated until the shadow of the structure has attained its narrowest transverse dimension. The latter procedure sometimes makes possible a differential diagnosis between a dilated tube and a tortuous one. The patient possessing the dilated aorta cannot be rotated into any position in which the shadow of the aortic arch does not seem wider than normal. The arch which appears wide in an anteroposterior view, as a result of tortuosity, is likely to possess a normal width when viewed laterally because the tube is not dilated. The lateral observation may be a difficult one to make particularly when the subject is obese and the hilum markings are much thickened.

Before speaking of the abnormal, it is perhaps best to describe the normal heart silhouette. Figure 1 represents the shape of the heart and great vessels as they lie in the thorax after the sternum has been removed, the lungs and pleura retracted, and the pericardium dissected away. It is evident that all of the chambers of the heart, except the right ventricle, form portions of the silhouette outline.

In considering the great vessels, it is important to remember that the superior vena cava casts little or no shadow on a roentgen-ray plate, and that the right border of the vessels, as shown in the roentgenogram, is in reality the right border of the ascending aorta. Comparison of this drawing (Fig. 1) with the cardiac outline shown in Figure 2 reveals the meaning of each curve in the roentgenogram, i. e., the right auricle below and the ascending aorta above form the right side of the shadow, while the left side is made up of

the descending aorta, the pulmonary artery, the left auricular appendage, and the left ventricle. Of course, not all of these structures are always sufficiently prominent to be made out. The pulmonary artery and the left auricular appendage rarely stand out so that they may be differentiated, except in disease of the mitral valve.

It is well in the beginning to establish the normal width of the aortic arch. This cannot be done with absolute accuracy, but within broad limits it may be said that for persons weighing between 100 and 200 pounds the greatest distance between the right border of the ascending aorta and the left border of the descending aorta, as seen on a 7-foot-plate, is normally between 4.5 and 6 cm.

CHRONIC ENDOCARDITIS

When the mitral valve is damaged, whether the lesion be stenosis, insufficiency, or a combination of the two, there results a derangement of the mechanical balance in the cardiac apparatus. After a time the auricles and pulmonary artery increase in size.

The left auricular appendage and the pulmonary artery may become so large that they overlie the left border of the descending aorta and extend upward to the crest of the arch. When this occurs, the supracardiac dullness is definitely increased to the left. This condition is well illustrated by Figures 2 and 3, which represent chronic cases of double mitral disease.

In Figure 2 the pulmonary artery has not become sufficiently enlarged to overlie completely the left side of the arch, but Figure 3 illustrates this more advanced condition. It is of interest

to note that the width of the aortic arch is 6.3 cm. in the first case, and 5 cm. in the second, while the actual width of the great vessels is considerably greater in both cases.

ARTERIOSCLEROSIS

Arteriosclerosis is primarily a disease of the intima, and consequently no great changes in the diameter of the aortic tube are to be expected. However, after fibrosis and calcification set in there may be a derangement of the course of the tube, especially when hypertension is present, and tortuosity of the aorta results. The appearance seems to suggest that the artery has increased in length. This tortuosity shows itself in the roentgenogram as an increased prominence of the aortic "knob" (that is, the portion of the ascending aorta which passes backward to the left of the spine just before becoming the descending aorta) and in a tendency of the descending aorta to swing well to the left of its normal position. In the oblique view the upper portion of the arch may be "clubbed," but the width in the midportion is usually normal. Calcified plaques can be shown only very rarely.

Figure 4 shows a tracing of the heart of a man past 60 years of age who had suffered from attacks of anginoid pain. The heart is not enlarged, the blood

Fig. 1.—Normal outline of heart and great vessels.

pressure is not elevated, and there is nothing normal made out on physical examination of the heart. No evidence of syphilitic infection is obtainable at present. The aortic arch is definitely widened, and the left border of the descending aorta lies to the left of its normal position. This finding, taken with the history of lead poisoning and the thickening of the peripheral arteries, points to the presence of arteriosclerosis.

The amount of arteriosclerosis as indicated by the shape of the aortic arch is slight in this case, and yet the presence of any sclerotic process in the arch makes it seem probable that an involvement of one or both of the coronary arteries may be causing the attacks of anginoid pain.

Figure 5 portrays the shape of the heart and great vessels of another man about 60 years of age who complains of no cardiac symptoms, and yet shows a marked tortuosity of the arch, an enlarged heart, and a high blood pressure. Here also are found a systolic murmur in the aortic area and an accentuated aortic second sound which accompany a diseased intima and a high blood pressure. The aortic arch measures 1.1

clinical signs of kidney damage are obtainable, and there is no evidence pointing to syphilitic infection.

Still another case of marked arteriosclerosis is shown in Figure 7. The symptoms in this case practically all point to sclerotic changes in the cranial vessels, and the laboratory findings indicate that the kidneys are damaged, also probably as a result of renal blood vessel changes. The roentgenogram shows a definite "knob" at the crest of the aortic arch, and the left border of the descending aorta swinging well to the left. The long diameter of the heart is increased. The vascular system in such a case would doubtless show extensive generalized sclerosis at necropsy.

SYPHILIS

The predilection of *Spirochaeta pallida* for the aortic arch is well known. Douglas Symmers⁹ found syphilitic aortitis in 55.7 per cent. of 314 old syphilitic cases coming to necropsy.

Arthur R. Elliott¹⁰ says:

From the practical clinical standpoint, accumulating evidence is forcing the conclusion that a persistently positive

Fig. 3.—Tracing in Case 2, double mitral disease with increased supracardiac dullness.

Fig. 4.—Tracing in Case 3, arteriosclerosis.

cm. more in this case than in the previously mentioned one, and yet there are no symptoms. This may be explained by assuming that the process is a diffuse one which has not involved the coronary arteries so much as the aorta itself.

The roentgenogram is of no direct value in ascertaining the condition of the coronary arteries, and is, therefore, of more diagnostic than prognostic importance. It is clear that the width of the sclerotic arch indicates little as regards the general condition of the patient, but it offers another link in establishing the diagnosis of arteriosclerosis of the aorta.

It is customary to look for arteriosclerosis in patients past 60 years of age, and yet the condition occasionally occurs in younger persons. Figure 6 shows the heart and great vessels of a woman of 39 who is known to have had hypertension and external signs of arteriosclerosis for six months. Here, as in Figure 5, the outlines of the "knob" are covered by a prominent descending aorta. It is very probable that the aortic tube itself is somewhat widened as a result of the hypertension. The heart is enlarged principally in its long diameter. The physical signs seem to indicate that this heart is very similar to the one shown in Figure 5. The only added feature is a relative insufficiency of the mitral valve. No definite

Wassermann reaction in a patient without evidence of syphilis in the skin, mucous membranes or nervous system points to the aorta as the next most probable seat of the disease.

Lenz writes that, in large cities, 25 per cent. of all syphilitic deaths is due to aortitis and its consequences.

Warthin is said to have discovered active lesions in the aorta of every case of latent syphilis that he examined.

Syphilis of the aorta is certainly not uncommon, but it is sometimes difficult to recognize. The process is likely to originate in the ascending aorta, often just above the aortic valve. The organisms enter the walls of the vessels by way of the vasa vasorum, destruction occurs after a time, and the stiffness of the wall slowly disappears. As a result, the pressure of the blood stream coming from the left ventricle causes a dilatation and change in outline of the great vessel. If the spirochete always limited its activities to one small portion of the aorta, the discovery of this localized dilatation by means of the roentgen ray would make the diagnosis fairly certain. However, different

9. Symmers, Douglas: Anatomic Lesions in Late Acquired Syphilis, J. A. M. A. 66: 1457 (May 6) 1916.

10. Elliott, A. R.: Syphilitic Aortitis, M. Clinics of N. Am. 1: 1305, 1918.

authorities give the percentage of cases of aortitis which is so localized as between 15 and 30 per cent. of all of those coming to necropsy. It seems possible that the percentage may be higher among the living, for it often takes more than a localized dilatation to produce death and bring the subject to the postmortem table.

Sir Clifford Allbutt¹¹ has called attention to cases of dilatation of the aorta noted in the French and British literature in which the etiology was thought to be rheumatic fever, septicemia, phlegmonous inflammation of the hand, and influenza. If such cases are authentic, they are extremely rare.

In most cases one is probably safe in assuming syphilis to be the cause of a localized bulging of the aorta, particularly when this abnormality occurs just above the aortic valve. Figures 8, 9 and 10 illustrate this type of case. Each roentgenogram shows a definite prominence at the base of the ascending aorta. Some of the signs of arteriosclerosis are also present, but early arteriosclerosis is not unusual in syphilitics.

The patient showing aortitis usually is between 30 and 50 years of age, and gives a history of infection some fifteen to twenty years previously. One expects

be dilated and is definitely wider than normal, but is also tortuous, and shows the characteristics of arteriosclerosis. The auscultatory findings, the blood pressure, and the condition of the peripheral arteries point to arteriosclerosis. There are two pulsating masses in other parts of the body thought to be aneurysms. The definite bulging of the ascending aorta to the right is more characteristic of a dilated tube than of a tortuous one. It seems probable that both arteriosclerosis and syphilis are etiologic factors in the production of this picture.

Syphilis of the aortic arch is usually a progressive process, and it may go on to one or more of three end-points, namely, aneurysm, partial or total occlusion of the coronary arteries, and sclerosis and retraction of the cusps of the aortic valve. Aneurysm, except when it occurs in some rare location, can be shown without difficulty on the roentgenogram. No direct evidence of involvement of the coronary arteries can be obtained; but when aortic regurgitation occurs, the increased length of the heart and the prominence of the curve of the left ventricle suggest its presence.

Figure 12 presents the combination of such a heart, with a wide aortic arch and the clinical signs of a

Fig. 5.—Tracing in Case 4, arteriosclerosis.

Fig. 6.—Tracing in Case 5, precocious arteriosclerosis with hypertension.

Fig. 7.—Tracing in Case 6, arteriosclerosis with nephritis.

to find a systolic murmur in the aortic area and also a diastolic murmur, together with a diminished or absent aortic second sound if the aortic valve is involved. It is often true that these signs may be elicited only in certain positions, with the lungs deflated.

Figure 10 is rather interesting because of the numerous diagnoses made. This woman was in and out of the hospital during a period of eight years, and the very multiplicity of diagnoses would argue against their correctness. Her precordial pain and dyspnea on exertion should have suggested the possibility of aortitis. This possibility was probably ruled out because of the negative Wassermann reaction; but it is now a rather general belief that a negative Wassermann reaction does not rule out syphilis.

It is the diffuse dilatation of the arch that offers the greatest difficulties in diagnosis from the roentgenologic point of view. Syphilis is not the only condition producing a wide aortic arch. When a diffuse dilatation does occur, it should be explained on the basis of the clinical findings and the patient's story. Figure 11 illustrates this point. The arch appears to

diseased aortic valve. It would seem reasonable to explain this picture by assuming that the widening of the arch occurred first as a result of a syphilitic aortitis, which process later extended down to the aortic valve, causing sclerosis and retraction of the cusps and giving rise to aortic regurgitation. Later, the increased load on the left side of the heart caused lengthening of the cardiac outline and hypertrophy of the left ventricle.

HYPERTENSION

Hypertension is often spoken of as a cause of dilatation of the aorta. The ascending portion receives the full force of the blood expelled from the left ventricle, which is usually much hypertrophied in cases of hypertension, so that it seems reasonable to expect a certain amount of stretching of the aorta. The process is in all probability a slow one, and the small number of cases studied indicates that it requires months rather than days for its completion. Smith and Kilgore,¹² in 1915, called attention to the wide

11. Allbutt, Sir Clifford: *Diseases of the Arteries*, Sect. 1, p. 143.

12. Smith and Kilgore: *Dilatation of the Arch of the Aorta in Chronic Nephritis with Hypertension*, *Am. J. M. Sc.* 149: 503 (April) 1915.

arches observed in a series of fourteen cases of chronic nephritis with hypertension. These patients had systolic blood pressures between 185 and 250, were between 30 and 50 years of age, and all showed negative Wassermann reactions.

Syphilitic aortitis is likely to occur between the ages of 30 and 50 years, and often is accompanied by some hypertension. Both conditions are therefore to be kept in mind when one is considering a widened arch in a person of middle age.

Arteriosclerosis in a more or less marked degree is not an uncommon finding in cases of hypertension, especially after the age of 50. The dilatation might be explained in some cases as a result of the influence of a high tension exerted against a weakened, sclerotic vessel wall.

Figures 13 and 14 show the hearts and great vessels of two patients with chronic cardiorenal disease, in which hypertension is an outstanding feature. The width of the great vessels is greater than normal in both cases. It is impossible to divide the left border into its component parts in this picture, and the border of the descending aorta cannot be definitely located. The aortic knob stands out prominently, and the heart

during normal breathing. Obesity in itself probably has no influence on the width of the great vessels. The cardiac outline shown in Figure 16 was traced from a 7-foot plate of an active, rather obese man weighing 220 pounds. The diaphragm was normally placed, and showed normal excursion when studied fluoroscopically. There was no abnormal width of the aortic shadow in this case. It seems, therefore, that a high diaphragm is in itself a cause of widening of the aortic arch. This fact should be kept in mind in such conditions as pregnancy, abdominal tumor, subphrenic abscess, ascites, extensive pleural adhesions, and extreme obesity.

DILATED PULMONARY ARTERY

The increased supracardiac dulness resulting from an enlargement of the pulmonary artery and left auricle in mitral disease has already been discussed. There are certain rare conditions in which the pulmonary artery alone is dilated; and when this occurs, the dulness extends much farther to the left than it should normally.

A striking example of this type of heart is shown in Figure 17. This man, aged 26, gives a history of

Fig. 8.—Tracing in Case 7, syphilitic aortitis.

Fig. 9.—Tracing in Case 8, syphilitic aortitis and tremor of syphilitic origin.

Fig. 10.—Tracing in Case 9, long unrecognized syphilitic aortitis.

is much enlarged, and presents a prominent left ventricular curve. The prominent knob suggests arteriosclerosis, and the part which that process plays in the widening of the shadow of the great vessels cannot be definitely stated. Suffice it to say that hypertension is at least a factor in the production of increased supracardiac dulness.

HIGH DIAPHRAGM

The frequency with which wide aortic arches occurred in obese persons who showed no definite evidence of cardiac disease made it seem probable that obesity might be related to the width of the great vessels. After some study it became apparent that the wide arches usually occurred in the type of patient who possessed a high diaphragm as a result of a large amount of abdominal fat. The outlines of three arches of this kind are shown in the upper portion of Figure 15.

The larger drawing in Figure 15 was prepared to show the effect of a high diaphragm on the width of the aortic shadow in a normally proportioned person. It is evident that the dotted outline traced from a plate made in full expiration is much wider than the solid outline, which represents the size of the great vessels

repeated pulmonary infection during the greater part of his life. The pulmonary second sound is markedly accentuated, and a definite shock, synchronous with the second sound, may be felt when the hand is placed on the chest in the precordial area. The electrocardiogram shows a definite right ventricular preponderance. These signs point to an elevated blood pressure in the pulmonary circulation which might produce a dilatation of the pulmonary artery. Such dilatation should produce a picture similar to that shown in Figure 17.

This case has been variously diagnosed as congenital heart, obstruction in the pulmonary circulation, and mitral stenosis. Be the diagnosis what it may, the roentgenogram seems to identify the enlarged pulmonary artery as the cause of the increased supracardiac dulness. Here, then, is a rare condition in the upper mediastinum which presents roentgen-ray evidence of no little diagnostic value.

DIFFERENTIAL DIAGNOSIS

The roentgenologist can draw some conclusions from his findings without clinical aid. The mitral type of heart and the type presenting a dilated pulmonary artery give rather typical silhouettes, and can usually be recognized. A high diaphragm is an evident condition, especially when viewed fluoroscopi-

cally. The sclerotic arch presents a prominent "knob" and descending portion when seen anteriorly: a clubbing at the crest and a normal width when seen obliquely. There are left the two conditions that produce dilatation of the aortic tube, namely, hypertension and syphilitic aortitis. A localized dilatation indicates the latter condition. A general dilatation may be due to either.

A large, hypertrophied heart accompanies a widened arch resulting from long continued hypertension. A diffusely dilated arch accompanied by a small normal, or slightly dilated heart is therefore likely to be caused by syphilis. Of course, after the syphilitic process has involved the aortic valve and the left ventricle becomes hypertrophied, the general appearance resembles that caused by hypertension.

In aortic regurgitation, the hypertrophy of the left ventricle is much greater than that of the right. In hypertension, both ventricles show hypertrophy to about the same degree. As a result, the distance across the base of the heart as well as the length is increased, and a generally enlarged organ results. The heart outline in regurgitation is increased downward and to the left, but the distance across the base (*B* in

only in those cases that show a localized prominence at the base of the ascending aorta.

It is the exception rather than the rule to find a single cause underlying increased supracardiac dullness.

The occurrence of syphilitic aortitis, arteriosclerosis, hypertension, and a high diaphragm in the same patient is not so very uncommon.

REPORT OF CASES

CASE 1 (231479, Fig. 2).—Double mitral disease.—A white man, weighing 172 pounds, had had an attack of precordial pain, not very severe, at the age of 12; gonorrhea at 17 and again at 18, and a second attack of precordial pain at 20. He drank much whisky, beer, tea and coffee. There was no history of children's diseases or tonsillitis. Seven months before examination he had been in bed one week with dyspnea, palpitation and precordial pain. There was no cough, edema, hemoptysis or fever. One week before he had had a more severe attack beginning with a feeling of constriction in the epigastrium followed by dull precordial pain and palpitation. He could sleep only in the sitting position. The pulse rate was 102. The sounds were irregular. The pulmonic second sound was greater than the aortic second sound. There was a loud, blowing, systolic murmur at the apex transmitted to the axilla. There was a short presystolic roll. There were no thrills. The systolic blood pressure was 100, the diastolic, 70. The arterial walls were not palpable. The renal function was 45 per cent., the Wassermann test, negative.

CASE 2 (233383, Fig. 3).—Double mitral disease.

—A white girl, aged 16, had had severe attacks of chorea at intervals during the greater part of her life, and pneumonia and pleurisy about a year before examination. She began to complain of nausea, epigastric pain, edema of the feet and hands, and dull aching pain in the hands, elbows and knees about four months before. About two months before, she began to have dyspnea, palpitation and precordial pain, and went to bed, where she had remained ever since. During the past three weeks there had been much vomiting, some cough, and a sharp knife-like pain between the scapulae. The patient weighed 98 pounds and possessed a very ruddy complexion which bordered on cyanosis. The tonsils were ragged and hypertrophied. The sounds were regular, rapid

and of fair quality. The pulmonic second sound was greater than the aortic second sound and accentuated. There was a presystolic roll at the apex followed by a soft, musical systolic murmur transmitted to the axilla. There was a thrill at the apex. The arterial walls were not palpable. The systolic blood pressure was 105, and the diastolic, 70. There was edema of the feet and ankles. The throat consultant noted that pus could be squeezed from the tonsils. The white blood count ranged from 13,000 to 14,000 per cubic millimeter. The Wassermann test and blood culture were negative. Roentgenoscopy revealed many pus pockets about the roots of the teeth.

CASE 3 (232013, Fig. 4).—Arteriosclerosis.—A white man, aged 62, had diphtheria at 9 years of age; scarlet fever (?) in childhood; gonorrhea at 20; pneumonia at 40; penile sores at 45, and painters' colic at 50. His wife has had three miscarriages and one stillborn child. He chewed tobacco, but did not use alcohol. Sensations of constriction in the chest accompanied by hot, swollen sensations in the hands began one and one-half years before examination. The attacks lasted only a few minutes, and occurred about once a week. Nitroglycerin gave relief. The attacks had been becoming worse and more frequent, and seemed to be brought on by exertion. They were now accompanied by dyspnea and palpitation. There was no edema. He was much more comfortable while in bed. The patient weighed 120 pounds. The cardiac impulse was seen and felt in the fifth space. The sounds were regular and of fair quality; not rapid. The pulmonic second sound equaled the aortic second sound; not accentuated. There were no murmurs or thrills. The

Fig. 11.—Tracing in Case 10, multiple aneurysms.

Fig. 12.—Tracing in Case 11, syphilitic aortitis and aortic regurgitation.

Fig. 1) is not much greater than normal. This difference is not always outstanding, but it sometimes gives a clue to the correct diagnosis in difficult cases.

This system of differential diagnosis seems simple and so it would be were it not for the fact that widening of the great vessels is practically never due to a single etiologic factor. Syphilis is quite often accompanied by arteriosclerosis. A certain degree of arteriosclerosis is a very common finding in cardiorenal disease with hypertension. The obese patient with a high diaphragm is the one most likely to show a high blood pressure, and he may also have a syphilitic infection. Obviously, the problem is not always a simple one.

SUMMARY

There has in recent years been an ever increasing tendency to use the roentgenogram in the diagnosis of syphilitic aortitis. That it is a very valuable adjunct to the clinical findings there can be no doubt; but I wish to emphasize the importance of a conservative interpretation of a widened shadow of the great vessels.

Arteriosclerosis, hypertension, chronic endocarditis, a high diaphragm, or a dilated pulmonary artery may give a similar picture, and it is perhaps wiser for the roentgenologist to suggest the diagnosis of aortitis

arterial walls were sclerotic. The brachials were not tortuous. The systolic blood pressure was 150; the diastolic, 74. The liver edge was palpable and slightly tender. The knee jerks were equal and active. The renal function was 60 per cent.; the urine, negative; hemoglobin, 75 per cent.; the Wassermann test, negative.

CASE 4 (233131, Fig. 5).—*Arteriosclerosis*.—A white man, aged 60, with no history of "rheumatism," and who denied venereal infection, had had some nocturia for several years, but no illness except attacks of pain in the right upper quadrant twelve years ago. These attacks were severe enough to require morphin. He now complained of burning pain in the right lower quadrant occurring in attacks during the past eight months. He had had occasional dizzy spells, but no dyspnea, edema, precordial pain, headaches or visual disturbances. He was well nourished and weighed 154 pounds. The heart sounds were regular and not rapid. The aortic second sound was greater than the pulmonic second sound and accentuated. There was a soft systolic murmur at the base transmitted to the neck. The systolic blood pressure was 220, and the diastolic, 110. The palpable arteries were sclerotic and tortuous. The pulse was of good volume and tension.

The urine showed nothing definitely abnormal. The non-protein nitrogen in the blood was 44.8 mg. per hundred c.c. The Wassermann test was negative. A cardiogram detected no ventricular preponderance.

CASE 5 (233568, Fig. 6).—*Precocious arteriosclerosis with hypertension*.—A white woman, aged 39, with no history of "rheumatism" or miscarriages, who denied venereal infection and whose "tubes and ovaries" had been removed eleven years before for pelvic abscess, had been weak and tired and subject to "hot flashes" and "cold sweats" since the age of 18. Dyspnea began three years before we saw her. About two years before she began to have palpitation and severe headaches accompanied at times by vomiting, dizziness, staggering and stars before the eyes; and on two occasions, everything turned black before her eyes. During the past year these symptoms had been less marked, but there had been some edema of the ankles, and a numb feeling in the right leg and arm at intervals. There had been no nocturia or other urinary symptoms. The patient was pale, and weighed 112 pounds. There was marked venous pulsation in the neck. The sounds were regular and rapid and of good quality. The aortic second sound was greater than the pulmonic second sound and much accentuated. There was a reduplicated first sound and a systolic murmur at the apex transmitted to the axilla. There was a systolic murmur in the aortic area not transmitted. Very questionable thrills were observed at the apex and at the aortic area. No presystolic murmur was detected. The arterial walls were palpable. The brachials were tortuous. The systolic blood pressure was 270 and the diastolic, 190, six months before, and now 210 and 140. The urine showed nothing abnormal except the slightest possible trace of albumin and rarely a white cell at numerous examinations. There was no fixation of gravity or retention of chlorids. The renal function was 60 per cent. Nonprotein nitrogen was 35.9 mg. per hundred c.c. of blood. The Wassermann test was negative twice.

CASE 6 (232022, Fig. 7).—*Arteriosclerosis with nephritis*.—A white man, aged 64, had had scarlet fever in childhood; was ill several months twenty years before we saw him with nausea, diarrhea, vomiting and abdominal pain; had had "grip" four years before, and generalized edema with headache, blurring of vision and delirium three years before. A "shock" occurred one year before, when he was uncon-

scious for twenty-four hours. There had been some weakness in the left arm and leg since. The patient denied venereal infection. He felt weak and tired. He still had weakness of the left arm and leg, and had attacks of dizzy sensations accompanied by vomiting, a feeling of pressure in the head, and a general numb feeling. He weighed 175 pounds. The pupils were irregular. The cardiac impulse was seen and felt in the sixth space. No thrills were heard. The sounds were regular and of fair quality, but rapid. The aortic second sound was greater than the pulmonic second and accentuated. No murmurs were detected. The arterial walls were palpable, the brachials not tortuous. The systolic blood pressure was 208, and the diastolic, 120. The knee jerks were normal. The urine, at two examinations, showed a trace of albumin, a specific gravity of 1.020 and 1.023, and frequent hyaline and granular casts. The renal function was 12 per cent. The Wassermann test was negative.

CASE 7 (Outpatient Department 392675, Fig. 8).—*Syphilitic aortitis*.—A negro man, aged 45, gave no history of "rheumatism." He had sore throats as a child. He drank much alcohol. He had gonorrhea at 25, and a penile sore at the same time that lasted for one month. He had had some precordial pain, occasional headaches, attacks of weakness and shortness of breath for the last year. He weighed 136

Fig. 13.—Tracing in Case 12, cardiorenal disease.

Fig. 14.—Tracing in Case 13, cardiorenal disease.

pounds. The pupils were equal, and reacted. The right epitrochlear gland was palpable. There was a systolic murmur at the apex transmitted toward the base and the axilla. The pulmonic second sound was accentuated. There was a short systolic murmur at the base transmitted to the neck. No definite diastolic murmurs were made out. The liver edge was palpable. The knee jerks were equal. The urine showed the least possible trace of albumin and a few white blood cells. The Wassermann test was negative.

CASE 8 (Outpatient Department 392688, Fig. 9).—*Syphilitic aortitis and a tremor of syphilitic origin*.—A white man, aged 43, had had typhoid, scarlet fever and gonorrhea; also a penile sore some years before. A slight tremor appeared in the left arm five years before, and remained constant and of the same intensity for three years. It then extended to the left leg and right arm, and for two years had been getting worse. There had been some shooting pains recently in the legs. Otherwise the patient felt well and strong. He weighed 140 pounds. The left arm showed a constant tremor. The right arm and left leg showed the same phenomenon to a less degree. The tremor diminished while purposeful movements were being performed. The right pupil was slightly irregular. There was no reaction to light and distance. There was a slight systolic murmur in the aortic area. The aortic second sound was greater than the pulmonic second sound. The systolic blood pressure was 170; the diastolic, 110. The lungs were negative. The knee jerks were absent. The blood Wassermann test was moderately positive. The spinal fluid

showed 31 cells per cubic millimeter, an increased pressure, and a strongly positive Wassermann reaction.

CASE 9 (Outpatient Department 181357, Fig. 10).—*Syphilitic aortitis long unrecognized*.—In 1911 a Jewish woman, aged 50, weighing 155 pounds, complained of continual cough with nonpurulent sputum, dyspnea, pain in the throat and back, and some incontinence of urine. The aortic second sound was accentuated; the heart was not enlarged to percussion. The systolic blood pressure was 150, and the bases of the lungs were full of râles. A diagnosis of bronchitis was made.

In 1912 the cough was still present, and was worse at night. The patient raised little and felt weak. No murmurs could be made out on heart examination. The blood pressure was noted as 130/80.

In 1913 the cough was worse but nonproductive. There was marked dyspnea on exertion. The aortic second sound was greater than the pulmonic second sound. A soft systolic murmur was heard in the aortic area. The blood pressure was noted as 135/90.

In 1914 the old symptoms were still present. Pain had appeared in the left part of the back and in the wrists and ankles.

In 1915 the systolic blood pressure was noted as 180. The patient was treated in the dental clinic for apical abscesses; in the throat room for pain in the throat, without a definite diagnosis, and in the orthopedic department for pains in the wrist and ankles. All of this treatment failed to clear up the original symptoms.

In 1916 the patient was admitted to the hospital for study. The Wassermann test was negative. After a week the patient was discharged with a diagnosis of: question of cholecystitis, chronic pyelitis, cystitis, and a question of mitral disease.

In 1917 the patient was admitted to the hospital the second time and was discharged with the diagnosis of senile heart, chronic arthritis, obesity and a question of myxedema. The blood pressure was noted as 140/90.

In 1919 the patient complained of hoarseness, cough, a feeling of anxiety, dyspnea, and some palpitation. The heart sounds were regular and distant; a systolic murmur was heard all over the precordia, transmitted to the neck; there was a diastolic murmur in the aortic area.

CASE 10 (231966, Fig. 11).—*Multiple aneurysms*.—A white woman, aged 50, who had been married thirty years, whose husband, she said, was well, who had had one child that lived to be 21 but died of tuberculosis, and four miscarriages, who had had no diseases of childhood, but "gastric catarrh," evidenced by abdominal distress and backache for many years, and who did not use alcohol, for the last five months had had an attack of dizziness and vomiting about once a week. The attacks lasted one or two days. She was well between the attacks. At times she had a pain in the back which was made worse by exertion and which on several occasions had been transmitted down the left arm and had been accompanied by tingling in the fingers. There had been progressive loss in weight, amounting to 70 pounds in four years, and the patient now weighed 100 pounds. A small, pulsating mass could be felt and seen in the base of the neck on the right side. A systolic bruit was heard over this tumor. There was a firm, round, somewhat tender pulsating mass in the right upper quadrant of the abdomen about the size of an orange. No bruit was heard over this tumor. The heart sounds were regular, rapid and of fair quality. The aortic second sound was greater than the pulmonic second sound and slightly accentuated. There was a loud, blowing, systolic murmur at the base, heard best over the aortic area and transmitted to the neck. There were no thrills. The

systolic blood pressure was 225, and the diastolic, 140. The arterial walls were palpable, tortuous and markedly sclerosed. The urine showed a slight trace of albumin and a few red and white cells at two examinations. The red count was 3,000,000. Hemoglobin was 70 per cent. The Wassermann test was negative.

CASE 11 (Outpatient Department 404570, Fig. 12).—*Syphilitic aortitis and aortic regurgitation*.—A negro, man, aged 61, had had pneumonia twice, and gonorrhea twenty-five years before. He had been married thirty years; the wife had never been pregnant. For about eight months he had been suffering from epigastric distress, dyspnea and palpitation on exertion. There was no edema. He weighed 185 pounds. The systolic blood pressure was 200; the diastolic, 80. The knee jerks were absent, the pupils sluggish. The brachial arteries were sclerosed and tortuous. The patient had a Corrigan pulse. There was a double murmur in the aortic area and a diastolic murmur to the left of the sternum. The aortic second sound was absent. There was a pistol shot sound in the groin. There were visible pulsations in the neck. At one examination, the urine was not definitely abnormal.

CASE 12 (231934, Fig. 13).—*Cardiorenal disease*.—A white man, aged 49, who had had diphtheria at 25, tonsillitis at the same time, and syphilis at the age of 20, and who did not drink steadily but who went on alcoholic sprees, reported that nocturia had begun one year before and had become progressively worse. Severe frontal morning headaches had begun seven months before; there had been attacks of

dyspnea during the last seven months; blurring of vision and spots before the eyes for the last three months; dizzy vomiting spells for the last two months, and cramps in the legs recently. The patient weighed 150 pounds. The sounds were regular and rapid. The pulmonic second sound was greater than the aortic second sound. There was a systolic murmur over the precordia heard best in the fourth left interspace. The pulses were equal and of high tension. The arterial walls were palpable. The systolic blood pressure was 210, and the diastolic, 140. The brachials were tortuous. The fundi showed albuminuric retinitis. The renal function was 10 per cent., the Wassermann test negative.

CASE 13 (233130, Fig. 14).—*Cardiorenal disease*.—A man, aged 52, who had no diseases except scarlet fever in childhood, who had always been a heavy meat eater, who used much alcohol until two years before, and who was a heavy smoker, began to complain of dyspnea and a "lazy" feeling about three years before. He had been in the hospital twice before because of a worn-out feeling. Orthopnea became noticeable two weeks before and was accompanied by nocturia and edema of the ankles, lower legs and thighs. There had not been precordial pain at any time. The patient weighed 196 pounds. In January, 1917, the sounds were regular and of good quality. The rate was normal. There was a soft systolic murmur at the apex. The second sounds were accentuated. The liver edge was palpable 2 cm. below the costal margin. An electrocardiogram disclosed left ventricular preponderance. The Wassermann test was negative. The renal function was 30 per cent. The urine showed a specific gravity between 1.020 and 1.024, albumin from a very slight trace to a slight trace, and many hyaline casts. The systolic blood pressure was 180, and the diastolic, 110. In May, 1919, the pulmonic second sound and the aortic second sound were equal. There was a shrill, high-pitched murmur in the mitral area. There was no thrill. The brachials were tortuous. The systolic blood pressure varied between 210 and 230; the diastolic was 140. The renal function was

Fig. 15.—Tracings in Cases 14, 15, 16 and 17, with widening of the shadow of the great vessels due to a high diaphragm.

from 20 to 25 per cent. The urine showed hyaline and granular casts and a specific gravity between 1.012 and 1.020. In October, 1919, the second sounds were accentuated. There was a blowing musical systolic murmur at the apex transmitted to the axilla. The radial arteries were sclerotic and beaded. The systolic pressure was 220, the diastolic, 150. There were râles in the bases of the lungs. There was edema of the ankles and thighs. The fundi showed sclerosed and tortuous arteries and small sclerotic plaques. The urine showed a specific gravity from 1.010 to 1.014, from a trace to a very slight trace of albumin, and hyaline and granular casts. The renal function was 25 per cent.; the hemoglobin, 70 per cent.

CASES 14, 15, 16 and 17 (Fig. 15).—Widening of the shadow of the great vessels due to a high diaphragm.—The three upper tracings represent the size and shape of the great vessels in patients weighing more than 200 pounds. In each case there was a high diaphragm probably the result of a large amount of abdominal fat. These sketches are traced from the 7-foot plates. In well-built persons weighing more than 200 pounds and possessing a normally placed diaphragm, the great vessels rarely measure more than 6 cm. in width.

The large drawing represents the shape and size of the heart, great vessels and thoracic cavity of a well-built man, aged 39, weighing 142 pounds. The solid outline was made from a 7-foot plate taken during normal breathing, while the broken outline was traced from a 7-foot plate of the same patient made during forced expiration. This man was a recently discharged soldier who had been leading an active life, and he had a good diaphragmatic excursion. During expiration the diaphragm rises and the chest walls are drawn in. The heart is forced upward, but apparently the upper portion of the aortic arch remains fixed. As a result, the heart and great vessels are compressed, and a widening of their transverse diameters results.

This patient came in complaining of a feeling of fullness in the chest which was worse after meals and had been present for about a year. There were no other symptoms. On auscultation there was a double murmur in both the aortic and mitral areas, and the aortic second sound was sharp. The pulse pressure was a little higher than normal. There was no rheumatic or syphilitic history. The electrocardiograph detected nothing abnormal. The patient was thought to have an early involvement of both the aortic and the mitral valves of rheumatic origin.

CASE 18 (Fig. 16).—An aortic arch of normal width in an obese man who possessed a diaphragm that was not abnormally high.—This tracing was made from a 7-foot plate of the heart of a young, active man weighing 220 pounds. He was not of an athletic type and showed considerable

Fig. 16.—Tracing in Case 18; an aortic arch of normal width in an obese man who possessed a diaphragm that was not abnormally high.

subcutaneous fat, but the diaphragm seen fluoroscopically was not pushed up abnormally high as a result of excessive abdominal fat. There were no symptoms, and the man seemed to be normal in every way.

CASE 19 (145038, Fig. 17).—Dilated pulmonary artery.—A white man, aged 26, who had croupous pneumonia at 12, typhoid and diphtheria at 13, bronchopneumonia (?) at 25, no history of "rheumatism," chancre (?) eight months before, who had been in the hospital with a "cold" for two weeks about four months before, who had been working but was never "up to snuff," and who had had some precordial pain and dyspnea for the last two years, had complained for the last four days of headaches, "hot and cold" sensations,

pains all over the body, and a cough accompanied by pain in the left lower chest. This condition was diagnosed as a mild bronchopneumonia. The patient weighed 124 pounds.

At the age of 12, the heart was outside the nipple line $3\frac{1}{2}$ inches from the midsternum. There was no increase to the right. The action was rapid and regular. The second sound at the apex was accentuated. The pulmonic and aortic second sounds were equal. There was a systolic murmur at the apex not transmitted. The patient had been in the hospital with croupous pneumonia at this time.

At the age of 13 the heart was in the fifth space in the anterior axillary line. There was no increase to the right. The action was rapid and regular. The pulmonic second sound was very much accentuated and equaled the aortic second sound. The first sound was replaced by a systolic murmur heard all over the precordia, loudest in the mitral areas and transmitted to the axilla. The spleen was palpable. The patient was in the hospital at this time with diphtheria and typhoid.

At the age of 25, the heart apex impulse was felt and seen 13 cm. to the left of the midsternal line. The sounds were regular and of poor quality. The pulmonic second sound was accentuated and reduplicated, and equaled the aortic second sound. A short systolic murmur at the apex was transmitted to the axilla. There was a short diastolic murmur just to the left of the sternum. The systolic blood pressure was 110, the diastolic, 60. Roentgenoscopy revealed a prominence of the pulmonary artery and a thickening of the hilum shadows and lung markings. A diagnosis of mitral insufficiency and bronchopneumonia (?) was made at this time.

At present, the impulse is heaving. A sharp slap is felt half way between the pulmonary area and the apex. The pulmonic second sound is greater than the aortic second sound and much accentuated. There is a soft systolic murmur at the apex. The second sound is loudest where the slap is felt, and is synchronous with it. There is no thrill. The systolic blood pressure is 148, and the diastolic, 110. The sputum shows the Type IV pneumococcus, and blood culture, *Staphylococcus albus*.

Fig. 17.—Tracing in Case 9, dilated pulmonary artery.

Children Born Out of Wedlock.—Questions about the legal obligations of parents and of the state to children born out of wedlock are answered in a bulletin entitled "Illegitimacy Laws in the United States and Certain Foreign Countries," issued by the Children's Bureau of the U. S. Department of Labor. Attention is called in this report to the fact that legal provisions for the support of the child born out of wedlock are inadequate—the payments prescribed are often too low, and in most of the states the period of support is too brief, sometimes reaching only to the child's tenth or twelfth year. The report suggests that illegitimacy legislation in the United States might be improved by uniform provision for the establishment of legitimacy; the legitimation of children of null or subsequent marriages; possibility of adoption by the father, and declaration that the relation of mother and child is the same whether the child is legitimate or not. In addition to a critical analysis of illegitimacy legislation in this country, the report contains an analysis of certain phases of the various state laws in tabular form, the complete text of all the state laws, the illegitimacy provisions of the codes of France, Germany and Switzerland, and a reference index to the U. S. illegitimacy laws.

ENCEPHALITIS LETHARGICA IN
PREGNANCY*

MARGARET SCHULZE, M.D.

SAN FRANCISCO

The case which I wish to report occurred in a pregnant woman of 35. In reviewing the recent literature, I have found records of only seven other cases of encephalitis lethargica occurring in pregnant women. In the nona epidemic of 1890, no cases complicating pregnancy are mentioned.

Though the fact is not always brought out in the smaller series, the disease appears to be far more common in the male sex than in the female, a point that was emphasized by Neal.¹ Of 189 cases in recent English and American reports, only sixty-seven occurred in women and girls, and of these only thirty-three were in women of the child-bearing age. The mortality is, however, considerably higher in women than in men. Of 122 men, seventy-two recovered, twenty-three died, and in twenty-seven the outcome of the disease had not been determined at the time of the report; of the sixty-seven women, twenty-seven recovered, twenty-four died, and in sixteen the outcome was not yet known. The mortality rate in the pregnant women appears to be particularly high. Of the eight recorded cases, including my own, one recovered, five died, and in two the outcome was not reported.

The first case in this series was reported by Harris.² This case occurred in the British epidemic in the spring of 1918, and was considered botulism, as were many of the earlier cases in England.

A young woman who was pregnant, almost at term, ate heartily of tinned salmon, March 28. The following morning she developed diplopia, bilateral ptosis, marked drowsiness, and pyrexia up to 103 F. She was delivered, April 2, without influence on the course of the disease, which had continued with double third nerve paralysis, drowsiness, pyrexia of 100 F., retention of urine and increasingly active delirium up to the time of writing. Examination of the suspected food had shown a large gas-producing, anaerobic gram-positive, probably spore-bearing bacillus which had not as yet been identified.

Duncan³ in May, 1918, reported a case of a married woman several months pregnant, who had been ill a few days. When first seen she was sitting by the fire-side with both eyes closed. She was dull, but spoke when she was addressed. She could raise her eyelids, the right more than the left. There was herpes of the upper lip. The outcome of this case is not stated.

Neal¹ has reported the only case with recovery at the time of writing.

This was a woman of 25 who was five months' pregnant. She had had an attack of influenza two weeks before the onset of the encephalitis, which began gradually with headache, chills and fever, vomiting, sweating and delirium. The spinal fluid showed great increase in cells and protein, a negative Wassermann test and negative guinea-pig inoculation for tuberculosis. Her condition remained the same for two weeks or more. Then she gradually recovered; the facial paralysis cleared up, and she had a normal delivery at term.

* From the Woman's Clinic, University of California Hospital.

* Owing to lack of space, this article is abbreviated in THE JOURNAL by the omission of introductory notes on the history of the disease. The complete article appears in the author's reprints.

1. Neal, Josephine B.: Lethargic Encephalitis, Arch. Neurol. & Psychiatry 2: 271 (Sept. 1) 1919.

2. Harris, W.: Lancet 1: 568 (April 20) 1918. McCaw, H. J.: Ibid. 1: 616 (April 27) 1918.

3. Duncan, J. W.: Brit. M. J. 1: 551 (May 11) 1918.

Sachs,⁴ in a series of seven cases, had three fatalities, of which two occurred in pregnant women. The duration of pregnancy is not stated in either case. In one there was a distinct history of influenza three months before the onset of the attack. Both of these cases presented all the ocular symptoms, the lethargy, and the ataxic and cerebellar symptoms. In one of the cases, in addition to the symptoms of poli-encephalitis superior, there was also marked wasting of the muscles of the upper extremity and tremor of the hands. One case showed a spinal fluid with 20 cells. Acetone and diacetic acid were present in the urine in both cases. Both patients were extremely toxic. The question of inducing abortion was considered but rejected, and it was very questionable whether anything would have been gained by it. The total duration of the disease in each case was about four weeks.

Putnam's⁵ case was in a woman of 26, who had had two previous normal pregnancies and whose present pregnancy had been normal.

She was found lying on the floor apparently asleep. When aroused, she was weak and dizzy and took no notice of her surroundings. She had no pain except a slight headache and no visual disturbances. Her face was expressionless and her eyes closed. The pulse was 114 and the temperature 99.4 F. The pupils were contracted and she tended to assume cataleptic postures. Her symptoms were at first thought merely hysterical, but her condition did not change, and the pulse rate and temperature remained elevated. Examination disclosed no paralyses, but some rigidity of the extremities and a slight Kernig reflex with some pain on full extension. The eye muscles and face were normal. The leukocyte count was 14,000; the urine was negative; the Widal test proved negative; the spinal fluid showed 11 cells, gave a negative Noguchi reaction and reduced Haines' solution. For the first few days, she awoke spontaneously for food and defecation; later she could be aroused for these functions.

She was delivered three weeks after the onset of her illness. She did not arouse during the four hour labor. The child was stillborn; its heart had not been heard the whole day previous. Four days after delivery the patient died.

Bassoe⁶ reports a fatal case with postmortem examination in a woman of 34, an octipara in the sixth month of pregnancy.

This patient complained of listlessness, fatigue and headache. She had some nausea but no vomiting, and moderate fever. The facial expression was dull, and there was a slight facial palsy on the right side. The protrusion of the tongue was weak. The back was somewhat rigid, the deep reflexes on the left side were increased, but there was no rigidity of the extremities. The pupils and eyegrounds were normal. She was mentally dull, slightly confused and disoriented for time. Five weeks after the onset of the disease, hyperpyrexia and pulmonary edema developed and the patient died.

Postmortem examination revealed marked congestion of the veins of the pia, with edema and congestion of the brain and minute hemorrhages visible on the cut surfaces, especially in the white matter of the centrum ovale and the basal ganglia. The ventricles and their ependyma were of normal appearance. Sections from the frontal lobe showed marked distention of the vessels, especially the veins, but there were only very small lymphocytic infiltrations around some of the smaller vessels. In the left motor cortex, the pia was loose in texture with slight increase of cells. There was no definite sign of inflammation in the cortex itself. The left optic thalamus showed very extensive inflammation with large collections of mononuclear cells about the distended vessels. There were no large hemorrhages. All the sections

6. Bassoe, Peter: Epidemic Encephalitis (Nona), J. A. M. A. 72: 971 (April 5) 1919.

of the pons showed marked inflammatory changes, most pronounced in the dorsal portion, with numerous small hemorrhages. The bulb showed no inflammatory changes.

REPORT OF AUTHOR'S CASE

The case which I wish to report is the following:

Mrs. N. A., a pregnant woman aged 35, entered the obstetric service of the University of California Hospital, April 23, 1919, complaining of edema of the legs and hands of one month's duration, and aching pains in both arms during the previous week. The pregnancy was one month past term. She had had one full term pregnancy six years before, complicated with marked edema, and some eye symptoms and pains in the legs during the last month, which had disappeared shortly after delivery. Her past history was otherwise negative. She had not had influenza, nor had any one in her immediate family.

Physical examination was negative except for the presence of a full term fetus in the left occipito-anterior position, varicosities of both legs with more edema of the legs than these could account for, and moderate edema of the hands.

Her mentality was rather low, but her mind seemed clear. Sensory examination disclosed a slight hyperesthesia to touch and pain over the posterior part of each shoulder; elsewhere sensation was normal. The pupillary reactions were normal. The deep reflexes were somewhat exaggerated, with a false patellar clonus. The left abdominal reflex was increased, the right was doubtful. There was a right sided Babinski reflex. Both hands showed a constant tremor, which increased if the patient tried to control it, but decreased if her attention was diverted. The blood pressure was 140 systolic and 95 diastolic. The urine showed the faintest possible trace of albumin with no casts. Both blood and urinary nitrogen were normal, and blood and urine cultures sterile. As all her teeth had been extracted dental roentgenograms were not taken and there were no other foci of infection demonstrable. The hemoglobin was 55 per cent. Sahli; the blood Wassermann reaction was negative. The temperature on the day of entry was 37.5 C. (99.5 F.), on the following day 37.2 C. (98.9 F.). After this it was normal for five days, until delivery. The pains in her arms persisted and at times were so severe as to require morphin for sleep. April 30, after five hours of normal labor, she was delivered of a child weighing 4,600 gm. (10 pounds). Following delivery she had a low grade fever, never higher than 37.6 (99.7 F.) and therefore not requiring a uterine culture. On the tenth day the temperature reached 38 C. (100.4 F.). It was now noticed that she had become very dull mentally and seemed in a sort of stupor most of the time. She was easily aroused, and when addressed answered rationally and was clearly oriented. She complained of diplopia, and said that the pain in her arms kept her awake at night. A slight ptosis of the left lid and a right sided facial paralysis developed. The Babinski reflex had now disappeared, the other reflexes and the sensory findings remaining about the same. There were no signs of meningeal involvement.

A spinal puncture, May 15, yielded a clear fluid under slightly increased pressure. The Nonne and Noguchi reactions were negative, the cell count was twenty-six and Fehling's solution was reduced. The Wassermann reaction was negative and cultures were sterile. There was no web. A second puncture, May 15, was again sterile. There was a moderate leukocytosis, varying from 12,000 to 18,000 with 80 per cent. polymorphonuclears. A nasopharyngeal culture showed *Bacillus influenzae*. The neurologic signs varied. She developed weakness of the muscles of mastication, tremor of the tongue with protrusion to the right, and then a right external rectus palsy.

About May 23, she began to improve markedly. Her mentality was much clearer, the tremor decreased, the tongue could be protruded normally, and the external rectus palsy was much less marked. The right arm reflexes were still increased, but the other reflexes were normal except for an atypical Oppenheim sign on the right side. The temperature became normal.

May 26, after getting up and walking about her bed without permission, she suddenly developed symptoms of pulmonary embolism and died in twenty minutes, twenty-six days after delivery.

Postmortem examination revealed thrombosis of both femoral veins and extensive bilateral pulmonary emboli, which occluded almost the entire pulmonary circulation. Macroscopically the brain was practically normal except for a few punctate hemorrhages on cut section in the region of the midbrain. The cerebrospinal fluid was normal in appearance and amount. Microscopic examination revealed the characteristic changes of lethargic encephalitis. There was congestion and slight round cell infiltration of the leptomeninges. There were marked perivascular infiltration and a few small hemorrhages about the vessels, especially of the midbrain and pons. There was no degeneration of the nerve cells. The medulla showed much less marked changes; the cerebral cortex was normal.

Clinical Notes, Suggestions, and New Instruments

ADMINISTRATION OF DIGITALIS BY "EGGLESTON METHOD"

CARY EGGLESTON, M.D., NEW YORK

Many requests have been received for information as to the practical application of this method of administering digitalis, and therefore it seems advisable to publish a brief statement regarding the details involved. The reader is referred to the original paper¹ for the data on which the method is based, and to the papers by S. Marx White and R. Edwin Morris,² and by R. Edwin Morris,³ for comments on the method.

This method of digitalis dosage and administration is designed especially for rapid digitalization by oral administration. It depends on the establishment of an average total amount of digitalis which is required to produce full digitalization, or the minor toxic actions of digitalis. This total amount is expressed in terms of the activity of the drug and the patient's body weight in pounds. The activity of the drug is determined by the cat method of Hatcher,⁴ described in the *American Journal of Pharmacy*, the unit being the weight of dry drug, in milligrams, which is required to kill 1 kg. of cat when a solution is injected slowly and continuously intravenously. This amount is called a cat unit. High grade specimens of digitalis, when not assayed by the cat method, may be regarded as having an average activity of 100 mg. to the cat unit. The average total amount of digitalis required for oral administration to man is 0.15 of one cat unit per pound of body weight.

CALCULATION OF AVERAGE TOTAL AMOUNT

The calculation of the average total amount required by any given patient may be as follows:

1. The patient's weight is determined in pounds.
2. The cat unit of the digitalis is determined.
3. One of the following formulas is applied:

$$\text{Formula I: } \frac{C. U. \times 0.15 \times W}{1,000} = \text{Grams of powdered leaf in total amount}$$

$$\text{Formula II: } \frac{C. U. \times 0.15 \times W}{100} = \text{Cubic centimeters of tincture in total amount}$$

$$\text{Formula III: } \frac{C. U.}{100} \times W = \text{Cubic centimeters of infusion in total amount}$$

In these formulas, *C. U.* is the number of milligrams in one cat unit, and *W* is the patient's body weight in pounds.

1. Eggleston, Cary: Digitalis Dosage, *Arch. Int. Med.* **16**:1 (July) 1915.

2. White, S. M., and Morris, R. E.: The Eggleston Method of Administering Digitalis, *Arch. Int. Med.* **21**:740 (June) 1918.

3. Morris, R. E.: Clinical Pharmacology of Digitalis, *Minnesota Med.* **1**:125 (April) 1918.

4. Hatcher, R. A., and Brody, J. G.: The Biological Standardization of Drugs, *Am. J. Pharm.* **82**:360, 1910.

The following example illustrates the use of these formulas: A patient weighs 150 pounds, and the digitalis available has an activity of 100 mg. to the cat unit. Applying Formula I for the powdered leaf, we have $100 \times 0.15 = 15$; $15 \times 150 = 2,250$; $2,250 \div 1,000 = 2.25 =$ grams of leaf in total amount. Applying Formula II for the tincture, we have $100 \times 0.15 = 15$; $15 \times 150 = 2,250$; $2,250 \div 100 = 22.5 =$ cubic centimeters of tincture in the total amount. Formula III gives $100 \div 100 = 1$; $1 \times 150 = 150 =$ cubic centimeters of the infusion in the total amount.

ADMINISTRATION OF AVERAGE CALCULATED TOTAL AMOUNT

1. When the patient has received no digitalis within the preceding ten days.

A. *In urgent cases.*—From one third to one half of the total calculated amount is administered at the first dose. After an interval of six hours, from one fifth to one fourth of the total is administered. After a second six hours, from one eighth to one sixth of the total is administered. Thereafter, if more digitalis is needed, about one tenth of the total may be repeated every six hours until maximal digitalization is secured. In the case of the example given above with the total amount being 22.5 c.c. of tincture, the first dose would be from 7 to 11 c.c.; the second from 4 to 5 c.c.; the third from 2.5 to 3.5 c.c., and thereafter about 2 c.c. every six hours if required.

B. *Rapid, for nonurgent cases.*—About one fourth of the calculated total is to be given at each of the first two doses, six hours apart. Thereafter about one tenth to one eighth of the total is given every six hours.

2. When the patient has been taking digitalis within the preceding ten days.

Before further digitalis is prescribed, the patient is to be subjected to the most careful examination, including the use of polygraphic or electrocardiographic records if available, to determine whether or not there are any evidences of digitalis action.

A. *When evidences of digitalis action are absent.*—The procedure is the same as outlined above, except that the total amount of digitalis required is to be reduced to 75 per cent. of the total calculated. Thus, in the example used the total would be reduced to 17 c.c. instead of the calculated 22.5 c.c., and the fractions prescribed at each dose would be based on the former figure (17 c.c.). The usual one tenth of the total every six hours may then be prescribed if necessary.

B. *When evidences of partial digitalization are present.*—It is best not to attempt to administer more than one half of the total calculated amount of digitalis, divided equally between the first three doses. In urgent cases in this group, however, one may administer 75 per cent. of the calculated amount, preferably in three equal doses, and then if digitalization is not quite complete, one tenth of the total amount may be prescribed every six hours.

SAFEGUARDS

The appearance of one or more of the following criteria of adequate digitalization, or of minor digitalis intoxication, indicates the cessation of further administration, either permanently or temporarily:

1. Nausea or vomiting (except when due to splanchnic congestion and present before treatment is begun).
2. Fall of heart rate (not pulse rate) to or below 60 a minute.
3. Appearance of frequent premature contractions; of definite heart block; of marked phasic arrhythmia, or of coupled rhythm.

The observance of a six-hour interval between doses allows time for complete absorption of the preceding dose and the development of its full action on the heart so that if the patient is examined just before the administration of each dose, dangerous intoxication can be absolutely prevented. In practice it is perfectly safe to give the first three doses without personally examining the patient before the second and third doses if the one nursing the patient is properly instructed to look for nausea, vomiting, or slowing of the pulse to 60 or less a minute before giving the succeeding dose, and to stop administration if any of these phenomena appear.

When a leaf, tincture, or infusion the cat unit of which is unknown is employed, 100 mg. may be taken as the cat unit; but not more than 75 per cent. of the calculated total amount should be given in the first three doses.

When the patient cannot be weighed, or when marked edema or general anasarca is present, the body weight (exclusive of edema fluid) must be estimated as closely as possible and the total amount of digitalis calculated as usual. Not more than 75 per cent. of the calculated amount should then be given in the first three doses.

COMMENT

The employment of this method of administering digitalis is without danger to the patient if the directions are followed in detail and if the safeguards are carefully observed. By its employment it is usually possible to produce maximal digitalis action in from twelve to eighteen hours, and marked therapeutic effects frequently appear within six hours after the initial dose. By its use it is possible to dispense with the intravenous or intramuscular administration of ouabain, amorphous strophanthin, or other digitalis body in the great majority of cases of heart failure.

412 West End Avenue.

TRANSFUSION OF "ANTIBACTERIAL BLOOD"; REPORT OF CASE *

GEORGE F. LITTLE, A.B., M.D., BROOKLYN

M. K., a girl, aged 11 years, whom I first saw, Nov. 3, 1918, in consultation with Dr. Paul E. Wesenberg, had been suddenly seized with epidemic influenza, October 28. In a few days there was evidence of pneumonia at both bases. November 3 there was well marked consolidation on the right side posteriorly. A similar condition soon showed on the left, and by the 7th the patient gave signs of massive consolidation of both lower lobes. The case seemed hopeless. Oxygen was used freely; the windows were kept wide open. Moderate doses of morphin, with large doses of atropin, were being tried out at one of the army camps, in cases of massive influenzal pneumonia. The patient was given $\frac{1}{24}$ grain of morphin sulphate and $\frac{1}{50}$ grain of atropin sulphate every four hours for a day, and every six hours the second day. Morphin was then discontinued and atropin reduced to $\frac{1}{100}$ grain at four hour intervals, replaced after a day or two by 4 minims of tincture of strophanthus. Three grains of caffein sodiobenzoate were administered midway between the doses of atropin and strophanthus. Three grains of camphor in oil, and 5 minims of a 1:1,000 solution of epinephrin were employed hypodermically, as conditions warranted. Eliminative measures were freely used.

After a few days of treatment, the lung consolidation lessened and the child slowly improved. At the end of two weeks, râles at both bases were the only finding. In the meantime, however, there were other complications: an acute laryngitis; a dry pleurisy of the upper right chest, and a suppurative glossitis. November 12, swellings were noted on the back, right thigh and both ankles. The right ankle was incised on this date by Dr. Wesenberg, and pus was found. A blood culture was ordered, and mixed influenza serobacterin was administered for several consecutive days, without noticeable benefit. Dr. Horace Greeley reported the culture as showing a staphylococcus and a bacillus, the latter not identified. On account of the patient's extreme weakness, he doubted reaction to an autogenous vaccine, and suggested transfusion of blood from a donor whom the vaccine might cause to react.

An incision in the left popliteal space, November 15, revealed a quantity of pus. On the 17th, an abscess in the lumbar region was opened. A first injection of autogenous vaccine was given on this day. Two days later, incisions showing pus were made in the right side of the chest, left arm, left forearm and right hip. A considerable quantity of mucus in the stools gave evidence of an enteritis. November 20. Dr. Max Bender tested the blood of seven family

* Read in part before The Brooklyn Pediatric Society, Dec. 13, 1918.

donors with that of the patient. In only one case was there no agglutination. On the following day Dr. George I. Miller made an attempt at transfusion. The donor had no visible veins at the bend of either elbow, and dissection brought to light veins of infantile size, capable of no flow of blood. Two days later the patient's left ear drum perforated.

Professional donors were tested and one found whose blood was available for the child. Three hundred c.c. were passed from vein to vein, November 23, by Dr. Miller and Dr. Benjamin E. Wolfort. Five-tenths c.c. of the patient's vaccine was then injected in each arm of the donor, with marked reaction.

At this stage of the case, the bronchopneumonia was of low grade, with some râles at the bases, apparently needing only increased resistance for clearance. The septicopyemia, however, was overwhelming, and the prognosis indicated a fatal outcome.

From the transfusion there was a slight general betterment. Both eyes, however, became infected. November 25, 400 c.c. of blood were transferred. The patient became cyanotic at the close of the operation, and in the following twenty-four hours the pulse was of poor quality, with a tendency to cardiac collapse. Possibly a little too much blood was passed. During the following week the temperature continued of septic type; the right ear drum perforated, and abscesses were reopened on the back and left arm.

December 3, 340 c.c. of blood were transfused, the donor having received 1 c.c. of vaccine in each arm four days previously. The child took the donation well, with apparent improvement in the general condition, but the temperature showed diurnal variation from 100 to 103 F. Incision, by Dr. Wesenberg, in the left popliteal space, December 5, brought pus in quantity. Drs. Miller and Wolfort again transfused, December 8, giving to the patient 390 c.c. of "antibacterial blood" from the donor, who had been "primed," as on the last occasion. There was difficulty in locating a receptive vein, the internal saphenous finally being utilized, after delicate dissection. Local anesthesia sufficed, as in previous transfers. Owing to prolonged procedures, apparently, the heart developed a condition requiring most active stimulation, and creating anxiety as to future interference. Cardiac weakness had been more or less a feature in the septic involvement. On the same date, the right ankle required incision.

Following this transfusion, the marked septic temperature curve disappeared, the râles at the bases cleared, and the patient took nourishment well and gained daily in flesh and strength. For months, however, while not in danger as to life, she was entirely disabled by continuance of local infections. Dr. Wesenberg incised at intervals—the right leg above the ankle, the right ankle again, the lower spinal region, the right side, the right ankle still again, and the left hip. January 2, and on several subsequent occasions, roentgenograms of the infected joints were taken by Drs. Eastman and Bayles. At the indication of the plates, Dr. Wesenberg, assisted by Drs. Edwin B. Wilson and Richard M. Mills, operated under general anesthesia, January 4. The right hip joint was opened; the head of the femur, displaced upward, was brought down, and the leg straightened and put in Buck's extension. The opening into the left knee joint permitted removal of dead bone. This leg was straightened and similarly extended.

Rib resection was called for, January 30, through development of an abscess of the lung. This apparently cleared up in a few weeks, but filled again and required reopening, February 28. Further operative measures became necessary, February 19, as roentgenograms revealed considerable destruction of the surgical neck and articular surface of the left femur. This hip had been opened and drained, February 3. The incision was enlarged by being carried transversely toward the rectum. Right hip drainage had ceased and the wound had closed: the presence of pus was apparent in the plates, indicating reincision. Lieut.-Col. Edwin H. Fiske, M. R. C., saw the patient in consultation, March 10. He did not advocate further operative interference. There was no additional development of localized infection. The

affected joints were slow in clearing up—the last to heal, the left knee, ceasing to drain in July. Limitation of motion was naturally expected, loss of function of the left hip being especially feared.

The outcome of the case, as shown in the present condition of the patient, is better than expected and reflects credit on the surgery. There is good motion in both hip joints. The right leg is shortened $1\frac{3}{4}$ inches; this is partly compensated for by a 1-inch shortening of the left leg; a thick shoe sole completes the balance. There is a right talipes equinus, probably capable of correction by tenotomy. A slight interference with the left knee flexion may be overcome.

COMMENT

The possible effect of several more transfusions on the local processes would have been of interest. It was not feasible, however, to go further.

"Antibacterial blood" seems worthy of trial in any severe general infection, other measures having failed of control.

CONCLUSIONS

Those in professional attendance certainly reached the conclusion that life was saved by the transfusions.

Possibly blood, without attempted action on it, might have accomplished the result. It is rational to conclude, however, that the patient's vaccine, injected into the donor, produced antibodies in his blood which were of specific value to the patient in overcoming her septicopyemia.

HITHERTO UNDESCRIBED SIGN IN DIAGNOSIS OF LETHARGIC ENCEPHALITIS

THOMAS F. REILLY, M.D., NEW YORK

While there is no great difficulty in arriving at a diagnosis in the cases of encephalitis presenting a history of double vision, ptosis and other cranial nerve phenomena, a not inconsiderable number of patients are encountered in hospital practice who are brought in unconscious or delirious, and from whom no such history is obtainable. In such instances the patient presents a picture closely simulating that of one in the third week of typhoid fever. There are no focal symptoms pointing to a local central lesion. The leukopenia, so frequently present, is also strongly suggestive of typhoid fever.

In children the picture is almost identical with tuberculous meningitis. I have noticed in the majority of cases of encephalitis a sign that is very startling when recognized. It consists of a rhythmic convulsive twitching of the muscles of the abdomen in the neighborhood of the eighth and ninth ribs. It often simulates the muscular movement of hiccup, except that it is one-sided. In two cases it involved the trapezius. Even in the conscious patient, it is beyond voluntary control. It has been present in the mild as well as in the severe cases, although in two patients it was not elicited when I observed them.

The term "lethargic" is unfortunate, as many of the patients having encephalitis are never lethargic; on the contrary, they are frequently delirious and often have choreiform movements of the limbs.

In some cases there are almost no cerebral symptoms, not even the ordinary placidity; in others a curious fear and apprehension may be evident, and again the patient presents only the painful sensations of an ordinary neuritis confined to certain peripheral nerve tracts, the central origin of which is evident by reason of its rapid transference to other regions of the border.

Often in these doubtful cases the convulsive twitching mentioned above is the only symptom that may serve to suggest that the patient is suffering from encephalitis.

It may be too early to regard this symptom as of absolute diagnostic value; but it has been present so frequently in the cases that I have observed that I am certain that it is at least a strongly suggestive sign.

SATURDAY, MARCH 13, 1920

INFLUENZA OF 1918 AND 1920

The epidemic of influenza in 1920 in this country reached its maximum, so far as the large cities of the country are concerned, in the week ending February 14. According to the Bureau of Census Reports, the number of combined deaths from influenza and pneumonia in that week was 7,059, while in the following week the number of deaths from these causes in the same cities had dropped to 5,088. These figures compare with the February weekly average in 1917 of 1,489. Although cases of typical influenza seem still to be appearing in various parts of the country, the peak of the epidemic has certainly been passed. As previously pointed out, the total mortality throughout the country has been much lower in 1920 than it was in 1918. Certain localities, however, have suffered quite severely, notably Kansas City, Minneapolis, Detroit, Milwaukee and St. Louis, all of which had a higher death rate from influenza and pneumonia than in 1918. Columbus, Ohio, and Indianapolis also suffered severely, although the actual excess rates did not reach quite as high a point as in 1918. Unofficial reports from small towns and villages show substantially the same conditions as observed in the larger cities. Most communities were less seriously affected than in 1918, but certain localities apparently without regard to geographic distribution were very seriously stricken.

The epidemic of respiratory disease of January, 1920, differed from the epidemic of 1918 in that the total number of persons affected was less, the proportion of acute rapidly fatal cases was smaller, and the period of the epidemic was somewhat shorter. Symmers,¹ in a study of the pathologic findings in a series of fatal cases of pulmonary disease of the recent recurrent epidemic in New York, noted certain clinical as well as pathologic differences between the types of the disease of the two epidemics:

The recurrent disease, while it incapacitated thousands, pursued a milder course, complicating pneumonias were relatively few, and the death rate, of course, did not approach the appalling figures of the previous eruption. On the other hand, the recurrent disease was characterized by a greater

variety of pulmonary lesions—among other things, by concomitant semipurulent pleural exudates, by multiple pleural and subpleural abscesses, by frequent and extensive purulent invasion of the interlobar and interlobular septums of the lungs, by the formation of solitary, oftener multiple, discrete or confluent abscesses of the parenchyma, and by an extraordinary range of pneumonic lesions.

This experience in New York was no doubt duplicated in many other localities, usually those in which the epidemic of 1918 was of like severity. In other communities the epidemic of 1920 presented a proportion of severe rapidly fatal cases approaching that of 1918. As was pointed out in these columns,² the case fatality in several large cities equaled that of the epidemic of 1918.

Apparently the differences between the original and the recurrent epidemic depended to a considerable extent on the relative susceptibility and exposure of the population of a community at a given time. The first wave of influenza in 1918 affected a large proportion of highly susceptible persons, and in these the course was particularly severe and fatal. The early fatal termination precluded the development of purulent complications, which require a somewhat longer time for development. The records in certain army camps showed that of those dying late in the epidemic, at a time when the proportion of purulent complications was larger, many had become ill early in the epidemic, but had survived their fellows only to succumb later to more slowly fatal complications. The effect of individual resistance on the type of pulmonary lesions has been noted by MacCallum³ in his studies on pneumonia following measles and on the pneumonias following influenza. Some communities suffered relatively little in 1918, and in some at least of these, in which there presumably remained a considerable number of highly susceptible persons, the influenza of 1920 produced many severe fulminant cases of the type seen early in the epidemic of 1918.

So far as now available, reports from different communities on the bacteriology of the 1920 epidemic show the same diversity of results as was the case in the 1918 epidemic. Symmers found *Streptococcus hemolyticus* in most of the lesions; *Staphylococcus aureus* was found occasionally in intrapulmonary abscesses. "In the pneumonic exudates themselves, the prevailing micro-organism was a streptococcus. In occasional instances, influenza bacilli and pneumococci were isolated in combination with one another or with streptococci." These findings resemble those of the later portion of the epidemic of 1918 in some army camps. On the other hand, Small and Stangl⁴ report from Chicago a higher proportion of Pfeiffer bacilli, in some of their groups from 75 to 100 per cent. In a group made up of cases of pneumonia chosen at

1. Symmers, Douglas; Dinnerstein, Morris, and Frost, A. D.: Differences in Pathology of Pandemic and Recurrent Forms of So-Called Influenza, J. A. M. A. 74: 646 (March 6) 1920.

intervals throughout the 1920 epidemic, pneumococci occurred in 84 per cent., hemolytic streptococci in 18 per cent., and Pfeiffer bacilli in 75 per cent.

In 1918, a clear bacteriologic picture of the epidemic as a whole was difficult on account of the diverse findings in different localities. However, the clinical features of the primary disease, influenza, were the same wherever it occurred, varying only in degree of severity, and there is much evidence in favor of the view that influenza has a demonstrable pathology of its own, as described by LeCount,⁵ Goodpasture⁶ and others, the outstanding features of which are capillary necrosis and hemorrhage, with resultant edema, and that the succeeding pneumonias result from infection by such organisms, whether streptococcus, pneumococcus, Pfeiffer bacillus, or others, as happen to be resident in the respiratory tract of the patient, and are able to grow on the soil prepared by the preceding influenzal lesions.

It seems probable that when complete reports of the 1920 epidemic are available we shall find that, on the whole, the severity is much less than in the epidemic of 1918, but that here and there groups of cases in 1920 were fully as severe and presented the same fulminant characteristics as in 1918. It should also be borne in mind that in larger communities, especially, there will be included with the cases of the epidemic influenza that group of cases of respiratory disease which would normally occur during the winter season, including a varying proportion of lobar pneumonias, streptococcal pneumonias similar to those of 1917-1918, and a host of cases of colds and tonsillitis which in nonepidemic periods would be passed with less remark.

IS FAT INDISPENSABLE FOR WELL BEING?

In a recent issue of *THE JOURNAL*, Hindhede⁷ of Copenhagen discussed the effects of the food restrictions that were imposed on the Danish people as a result of the blockade existing during the latter years of the war. Despite the fact that Denmark was a noncombatant neutral nation, the interference with the international transfer of food, brought about by the food administrations of the allied governments and the shipping situation, prevented the importation of the usual quota of bread cereals and of the large amounts of cattle feeds that had been used before the war to maintain the stock of domestic animals used directly as food or kept to supply dairy products. Although the situation was somewhat similar in Germany, it would appear that the outcome of the shortage was far more serious in the latter country than in Denmark. The greater success attained in Denmark in maintaining the populace in health under unexpected changes in

food supply is attributed to what Hindhede commends as the wiser policy of a government "converted to the newer ideas on nutrition."

We shall not review at this time the various methods suggested by the nutrition experts of the affected countries for meeting the emergencies that arose. They have become the subject of somewhat acrimonious debate between the adherents of different schools of physiologic thought. Essentially, the plan of the Danes consisted in reserving the available cereals, notably rye, wheat and barley, as well as a large proportion of the potatoes grown in Denmark, for the people themselves instead of feeding them to the domestic animals, particularly cattle and hogs. As a consequence of this decision to use the vegetable products directly instead of first converting them into animal tissue for human consumption, so many of the hogs were killed that the number of swine in Denmark was soon reduced to one fifth of the prewar stock. Consequently the supply of meat was greatly reduced, and likewise that of fats, which are derived so largely from animal products.

This scheme involved the placing of the Danish nation on a preponderatingly vegetarian basis. Almost inevitably this necessitated a lowering of the protein content of the dietary. In addition to this, furthermore, there resulted a large deficit in the fat content of the ration. To prevent an unduly low protein intake, the cereals were milled only slightly, so as to retain a maximum of the outer nitrogenous layers, which are commonly removed in the preparation of barley, wheat and rye for human consumption. Wheat bran was actually added to flour to increase the protein content of the bread made from it. "Bran," Hindhede writes, "was considered to be a very valuable food, one which was well digested by man."⁸

In this respect the reports differ from the experience of American investigators. They have repeatedly found that the amount of protein digested varies in flours according to the character of the particles of the bran. In a recent series of experiments on man at Washington,⁹ the bran protein itself was digested to the extent of 44 per cent. in the case of fine bran only, whereas nearly three quarters of the protein of coarser wheat bran remained unutilized. Although it is safe to say, in harmony with recent observations of Langworthy and Deuel,¹⁰ that the finer a bran-containing flour is ground, the more completely it is utilized by the human body, yet American physiologists would probably hesitate to urge a very liberal inclusion of bran in the dietary as a source of protein. Indeed, bran has acquired a quite different significance of late among physicians.¹¹

Another outcome of the Danish regimen will seem far more significant to most readers. "While fat was regarded as a very valuable addition to the dietary, it was not considered as being necessary."⁷ This thesis, which has been defended by Hindhede for several years,¹² is likely to meet opposition from many, particularly those who have attributed some of the types of malnutrition consequent on "war diets" to lack of fat in the ration. Nevertheless, Hindhede¹² has furnished the records of a number of persons who have actually been maintained for many months in good health and vigor on diets of bread, potatoes, vegetables and fruits without any added fat whatever. It might seem as if we were face to face with an inexplicable contradiction here, especially since it is now believed that a fat-soluble vitamin plays an important part in nutrition, at least in the periods when growth or tissue production are concerned. Recent developments in the study of the physiologic value of different foods may give a clue to a possible explanation. So long as the fat-soluble vitamin (fat-soluble A) was supposed to be present only in natural fats and oils, it seemed inevitable that some modicum of suitable fat should be furnished in the diet. However, the studies of McCollum¹³ and particularly the more recent investigations of Osborne and Mendel,¹⁴ and of Steenbock¹⁵ and his co-workers, have clearly demonstrated that the vitamin under discussion is present in considerable abundance in many vegetables. Herein may lie the answer to the possibility of successful nutrition on diets poor in fats. The Danish ration is said to have abounded in vegetables. Doubtless in other places during the war the lack of fat-soluble vitamin was averted during stringency in the fat supply when milk, butter, eggs, and other animal sources of this food factor were lacking, by the inclusion of vegetables, notably cabbage and similar products, in the ration. Whether fat as such, apart from the other substances which it may include in solution, is an indispensable in nutrition is still an unanswered question. Hindhede's investigations have brought it into new prominence.

QUININ: 1820-1920

In the *Paris Journal de Pharmacie* of May, 1820—a hundred years ago—Joseph Pelletier, professor at the *Ecole de pharmacie*, who two years earlier had discovered strychnin, stated in a letter to one of the editors:

I take occasion to announce in your journal, in the name of MM. Labillardiere, Caventon and myself, the discovery of a base ["une substance alcaline"] in gray cinchona. This is perhaps the substance which Gombès first found and named cinchonin, or the pure resin obtained by Laubert; but these chemists did not recognize the true character of the sub-

stance for which the basic nature remained to be discovered and most of the properties to be investigated. The yellow cinchona likewise contains a substance capable of combining with acids and forming crystalline compounds; but this substance differs from cinchonin (the base of gray cinchona) in several features.

Soon after the successful chemical isolation of the two distinct alkaloids, quinin and cinchonin, in the different kinds of cinchona bark which had up to the beginning of the nineteenth century been used in its crude powdered state, although many efforts were made to discover the medicinal principles therein, Pelletier established a factory for the production of quinin. From there the demand of the world for the isolated drug was thus supplied until, in 1826, J. D. Riedel began the preparation of quinin in Berlin. This venture was not very successful, owing to the failure of the producer to recognize the variability of alkaloid in the cinchona bark. Later Zimmer of Frankfort engaged more successfully in competition with the French trade.

The cinchona alkaloids, of which twenty or more have been described, have been termed "a South American gift to humanity."¹ It is related that in 1640 the Count of Clinchon, who was at the time viceroy of Peru, returned to Spain with his wife, who took with her a quantity of the medicinal cinchona bark and thus was the first person to introduce it as a specific into Europe. Until 1867, English manufacturers were entirely dependent on South American sources for their supply. Uncultivated trees in Bolivia, Peru and Ecuador furnished the bark. In that year the first importations of cultivated bark arrived from India.

The year 1920 marks the centenary of the first isolation of the most valuable alkaloid of the cinchona bark. Its therapeutic virtues need not be extolled to medical readers. In 1826, Pelletier and Levaillant together produced about 177 kilograms (390 pounds) of salts of quinin.² During the year ending in June, 1914, the United States alone imported cinchona bark to the amount of 3,648,868 ounces, valued at \$464,412, and quinin sulphate and other alkaloids or salts of cinchona bark to the amount of 2,879,466 ounces, valued at \$624,125.¹ If medicine were to think of quinin in relation to malaria alone, not to mention the value of the drug in the management of other diseases, she would well be justified in pausing to give worthy recognition to the French pioneers in pharmaceutical chemistry who first gave her this useful therapeutic product in isolated form a hundred years ago.

Hazardous Occupations.—The physical reexamination of workers in hazardous occupations will result in the accumulation of scientific facts of known value with which to replace the oftentimes erroneous opinions now held regarding the dangers and hazards of certain occupations.—F. L. Rector: *Public Health Rep.*, Jan. 9, 1920.

Current Comment

PUBLIC HEALTH ORGANIZATION AND THE MEDICAL PROFESSION

It will probably still be a long time before the desirability of protecting the public health will make the same appeal to the legislators controlling public funds as does the necessity of protecting property. Nevertheless the tendencies of the times are making it almost impossible for even the most unprogressive community to fail to take notice of the growing demands for greater and better service in the interest of public health. The health officer of a decade ago, and the board of health to which he was responsible, are undeniably experiencing an evolution into something more active, more efficient and more important than they were in the past. In the coming years our communities will no longer be satisfied with merely the control of epidemics and the proper disposal of garbage and other wastes as the work of their health experts. Professor Winslow¹ of Yale, in an illuminating vice presidential address before the American Association for the Advancement of Science at St. Louis, forecast the future of the movement for greater accomplishment in the domain of public health by thus defining its scope:

Public health is the science and art of preventing disease, prolonging life, and promoting physical health and efficiency through organized community efforts for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene, the organization of medical and nursing service for the early diagnosis and preventive treatment of disease, and the development of the social machinery which will insure to every individual in the community a standard of living adequate for the maintenance of health.

This represents no mean program. It calls for a corps of experts rather than a single officer, who has in too many instances in the past been as untrained as he has been underpaid. With the physician, the earliest health officer to be recognized in the development of the public health field, the bacteriologist was the first to become affiliated for greater usefulness. Subsequently came the epidemiologist, trained "to trace out the subtle pathways of infection by which they spread from one person to another through the complex web of community life." The public health nurse, who has already more than justified her special province, is likewise here to stay; and Winslow will not permit us to be content until the sanitary engineer, the statistician and the social worker are included in the coterie of highly qualified persons who must cooperate to make of the movement for public health, as defined, something as influential and wholesome as are the conservation and development of mental efficiency in the educational organizations of the country. He would be blind, indeed, to the forces of progress who would deny that these things may come about. The public health campaign is going forward rapidly. It will be interesting to observe how its outcome affects the medical profession in the com-

ing years. We must not be blind to the fact that the ordinary physician alone cannot and will not be expected to carry forward the new projects in their entirety. The public health physician must already be specially trained for his duties if he is to rise above the level of mediocrity in the work. Sanitary experts and others without special training in clinical medicine must find a place in the new scheme of organization. Who can foretell how the plans and performances of the "sanitary statesmen" of the coming generation will modify the practice of medicine?

GAS CYSTS OF THE INTESTINE

The difficulties of abdominal diagnosis are already so great that it seems almost criminal to call attention to any new conditions that must be taken into account in reaching a conclusion as to the nature of a given case of disease in the abdomen. Since 1876, when Bang of Copenhagen described the first case in the human being, the literature has contained an increasing number of references to a peculiar abdominal condition characterized by the formation of multiple gas-containing cysts in connection with the peritoneum and the walls of the stomach and the intestine. Tuffier and Letulle¹ have recently described two new cases and discussed both the clinical manifestations and the pathologic anatomy of this strange malady. There is nothing characteristic about the symptomatology of the disease. Many of the patients have no symptoms whatever, and the presence or absence of symptoms depends on the location of the process and its mechanical effect on the stomach and intestine. Those patients who have symptoms complain of digestive disturbances, such as diarrhea and vomiting, and finally present the picture either of intestinal obstruction or of an abdominal neoplasm. Such cases usually fall into the hands of the surgeon who, on opening the abdomen, finds large numbers of gas-containing cysts connected with the peritoneum or digestive canal which may be of sufficient size to cause intestinal obstruction or to produce a palpable tumor. A few cases in which a second operation has been necessary have demonstrated the strange fact that the mere opening of the peritoneal cavity and handling of its contents results in the disappearance of the cysts. This at least is one explanation of such observations, although another possibility is that the disease naturally tends to recovery after a certain length of time. The studies of Letulle² on the pathology of the condition show that the primary lesion is an inflammation which involves the peritoneal lymphatics, causing obstruction in some places and dilatation in others. The mysterious aspect of the process is the origin of the gas with which the cysts are filled. This gas consists of various combinations of carbon, oxygen and hydrogen. It is quite odorless, and obviously is not of intestinal origin. Nobody has yet been able to bring forward any reasonable explanation of its presence, although no very

1. Tuffier and Letulle: Sur une maladie caractérisée par des kystes gazeux de l'abdomen, *Bull. de l'Acad. de méd.* 82:5 (July 1) 1919; abstr. *J. A. M. A.* 73:795 (Sept. 6) 1919.

2. Letulle, Maurice: Les kystes gazeux de l'intestin et du péritoine, *Presse méd.* 27:781 (Dec. 20) 1919; abstr. *J. A. M. A.* 74:494 (Feb. 14) 1920.

1. Winslow, C.-E. A.: The Untilled Fields of Public Health, *Science* 51:23 (Jan. 9) 1920.

careful bacteriologic studies seem to have been made. Tuffier and Letulle do not seem to consider the condition analogous to the gas cysts of rapid formation which are sometimes found in the intestinal wall in connection with the gas bacillus. It would seem, however, that the bacteriologic side of the disease should be carefully investigated, as bacterial action seems to be the most likely explanation of the formation of the gas.

THE REACTION OF THE SWEAT

Although it has been taught that the skin is an organ of excretion in cooperation with the lungs and kidneys, there seems to be little evidence to substantiate the importance of the cutaneous tissue in this function. There is no uncertainty, of course, regarding the liberal output of water that may occur by way of the skin through the agency of the sweat-glands; but this loss of water is mainly determined by the need for regulating the temperature of the body. Variations in external temperature or the work done and heat produced by the body, rather than the quantity of the fluid intake, determine the extent to which perspiration takes place. There is a small quantity of nitrogenous waste present in the sweat. Its quantity is, however, too small to play any significant part in the excretory functions. The same conclusion applies to the small content of saline constituents which have been discovered in the secretion from the skin. In speaking of the popular overestimation of the share of the skin in the removal of waste, Stiles¹ has naively remarked that the belief that "the pores must be kept open" lest poison gather in the system has been so fruitful of wholesome practices that one is reluctant to question it. Nevertheless, it is perhaps too soon to dismiss entirely the possibility that the skin may play some part, even if only a minor one, in the regulatory functions other than that of heat regulation. Our knowledge of the composition of the sweat is still all too meager, particularly so far as it may be varied by changes in the condition or activities of the organism. For example, the statements as to the reaction of sweat have been conflicting. Obviously if the skin, like the kidneys, is to be considered as engaged in removing the undesirable waste from the body, one would expect an acid excretion since a preponderant number of the end-products of metabolism are acid in character. Recent experiments on man by Talbert² leave no doubt as to the acid reaction of sweat. It matters not whether the secretion is caused by work or by heat; in health it is acid, and the degree of acidity is greater than has been assumed. This reaction, which is represented by a hydrogen-ion concentration of $p_{H} =$ from 5 to 6, is not due to products from the sebaceous glands which have, in the past, sometimes been charged with causing the result; but why, as Talbert found, the sweat caused by external heat is always more acid than that provoked by muscular effort remains a physiologic mystery.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Personal.—Dr. George E. Goodrich, Phoenix, has been appointed state superintendent of health.

Plans for Sanatorium.—A number of physicians of Casa Grande are planning to carry out a tuberculosis sanatorium project. The site for the enterprise is half a section of land northeast of Casa Grande on a mesa. On this site it is proposed to build 100 houses each to cost about \$3,000 furnished and to be rented to families and individuals at \$50 a month. This will include the service of a resident physician. There will also be constructed a hospital, an electric light plant, an office building and an experimental laboratory.

CALIFORNIA

Chiropractic Measure on Ballot.—With 55,094 signatures (47,744 of which are of residents of Los Angeles) the chiropractic initiative measure has qualified for a place on the ballot at the next general election in California. The measure contemplates creating a chiropractic board and providing for the licensing of all chiropractors now in practice.

Chiropractors Arraigned.—Linden L. D. McCash, chiropractor of Berkeley, has been arrested on a charge of practicing without a state medical certificate.—It is reported that E. Burnard Hubley, a chiropractor of Los Angeles, was found guilty of practicing without a state license, February 5. He was arrested about a year ago on a similar charge and found not guilty.

CONNECTICUT

Tuberculosis Clinic.—The board of health of New Haven, February 24, voted to establish a tuberculosis clinic at Grace Hospital, New Haven, as soon as arrangements could be made with the hospital authorities, and the board of finance sanctioned the expenditure, which is estimated at about \$3,000.

New Officers.—At the annual meeting of the New Britain Medical Society, Dr. Walter J. Robbins was elected president; Dr. Frederick J. Mann, vice president, and Dr. George W. Dunn, secretary-treasurer.—New Haven County Medical Society at its annual meeting held, January 21, was given a bust of Dr. Jonathan Knight by Dr. Louis M. Gompertz and Donald W. Carmichael. The following officers were elected: president, Dr. Robert E. Peck; vice president, Dr. Raynham Townshend; recording secretary, Dr. Frank L. Phillips; corresponding secretary, Dr. Samuel J. Goldberg, and treasurer, Dr. Frank H. Wheeler.

Personal.—Dr. George Blumer, New Haven, for thirteen years in service as professor of medicine at Yale University Medical School, has requested to be relieved from duty at the close of the academic year. His resignation has been accepted. Dr. Blumer was chosen dean of the school in 1910, and during his deanship the annual budget has increased from \$43,000 to \$225,000 and the endowment from \$225,000 to \$2,700,000. Dr. Blumer desires to be relieved of the burden of administrative duties in order to devote time to his consultation practice.—Dr. Clarence E. Skinner, New Haven, has been made medical director of the Postal Life Insurance Company, New York City.—Dr. Edward H. Kirshbaum, Waterbury, has been appointed medical examiner (coroner) for the town of Walcott, succeeding Dr. Edward W. Goodenough, resigned.

GEORGIA

Sanatorium Taken Over by Government.—The formal transfer of the Cheston King Sanatorium, Peachtree Road, Atlanta, has taken place and the hospital is now known as the U. S. P. H. S. Hospital No. 48.—Lenwood Hotel, Augusta, has been leased to the United States government for use by the Public Health Service in the care of disabled soldiers.

ILLINOIS

Physicians Will Not Prescribe Liquor.—The members of Will County Medical Society at the meeting, March 3, agreed not to prescribe liquor in their practice.

New Government Hospitals.—The Livingston Hotel and the laboratories of the Leslie E. Keeley Company, Dwight, have been leased to the U. S. Public Health Service and will be converted into a hospital with accommodation for about 200 patients.

Venereal Disease Statistics.—Among the 11,915 cases of venereal disease reported to the Illinois State Department of Public Health during the year ended June 30, 1919, 656, or about 5.5 per cent. of those affected, were employed in the handling of foodstuffs. Of the total number, 7,756 were males and 4,159 females.

Personal.—Dr. Edwin B. Godfrey, Springfield, sailed from New York, February 26, for the Balkan States for service as major in the Medical Corps of the American Red Cross. —Dr. Letitia A. Westgate, Aurora, formerly city chemist and bacteriologist of Aurora, is reported to have sued the city for \$30,000 damages.

Chiropractor Fined.—Joseph Langley, La Harpe, is reported to have been arrested recently for practicing medicine without a license and was fined \$100 and costs. Langley's advertisement to sell "a six months' practice, yielding over \$200 monthly," was called to the attention of the Department of Registration and Education and led to his arrest. Langley, it is said, had paid \$100 for membership in the Illinois Association of Chiropractors and had been assured that such membership would protect him in his practice. After his office had been closed and his signs had been taken down by order of the court, Langley said he was going back to Burlington, Iowa, "where it was not necessary to have a license to practice chiropractics."

Chicago

Chicago Woman Appointed Chief Nurse.—Miss Helen Scott Hay, formerly superintendent of the Illinois Training School for Nurses and chief nurse of the Red Cross commission to the Balkans, has been appointed chief nurse to the American Red Cross Commission in Europe.

Haggard in Chicago.—Dr. William D. Haggard, Nashville, Tenn., presented a paper before the Chicago Medical Society at its meeting, March 10, on "The Consideration of the Toxic Non-Exophthalmic Goiter," illustrated by lantern slides. An informal dinner in honor of Dr. Haggard was given at the University Club, preceding the meeting of the society.

Pathologists Meet.—At the meeting of the Chicago Pathological Society and section on pathology of the Chicago Medical Society held, March 8, the subjects of discussion were: ectopic pregnancy, hydronephrosis and lymphatic tumors. A new anaerobic technic was demonstrated and an improved method of cultivating gonococci under partial oxygen-tension was described.

Personal.—Dr. Saul A. Koppnagle, national organizer and secretary of the Chicago chapter of the Communists Party, surrendered, March 3, and gave bonds of \$10,000 in answer to the charge of conspiracy to overthrow the government. —Dr. John H. Curtis has been selected as superintendent of the New Britain (Conn.) Department of Health, succeeding Dr. William M. Stockwell, resigned.

Prescription Doctor Arrested.—R. M. Carroll, charged with having issued promiscuously prescriptions for whisky, was arraigned, March 4, and held in bonds of \$2,000. It is claimed that this man issued at least 200 prescriptions a day and claimed that he charged "anywhere from \$1 to \$7 for the prescription, depending on the condition of the patient's cough." —Dr. Joseph A. Khamis, held on the charge of violation of the liquor law, protested that he had not written prescriptions without thoroughly examining the patient, and said that he had been robbed of a number of signed prescription blanks by men posing as revenue officers.

KENTUCKY

All-Time Public Health Service.—Davies, Christian, Scott, Boyd and Harlan counties have taken advantage of the offer of the state board of health to appropriate \$5,000 annually to establish an all-time public health service provided a like amount is subscribed by the county.

Board of Health Appointments.—The following have been appointed members of the state board of health: Dr. Isaac A. Shirley, Winchester, 1918-1923; Dr. William W. Richmond, Clinton, 1918-1923; Dr. Joseph E. Wells, Cynthiana, 1919-1921; Dr. John G. South, Frankfort, 1920-1925, and Dr. George S. Coon, Louisville, 1920-1925.

MARYLAND

Negro Staff for Colored Schools Appointed.—Dr. C. Hampson Jones, Baltimore, commissioner of health, has announced the selection of a staff of negro physicians and nurses for medical inspection of negro schools.

Coroners Appointed.—The following coroners for Baltimore city have been appointed by Governor Ritchie: Drs. James M. Fenton, Henry L. Sinskey, John J. Morrissey, Jr., Harry K. Gorsuch, William T. Riley, Otto M. Reinhardt, James K. Insley, Jay T. Hennessy and George C. Blades.

New Hospital Opened.—The Morrow Hospital, Baltimore, opened February 18. The institution is for the advancement of social hygiene and the treatment of venereal disease, and is under the charge of the United States Public Health Service, the State Board of Health, and the Health Department of Baltimore.

Johns Hopkins to Get Appropriation.—The general education board of the Rockefeller Foundation has announced from its New York office that an appropriation of \$400,000 is to be made to Johns Hopkins University. The money will be devoted to the women's clinic, which will be built in the spring. This amount was promised by the board last year if the university could raise \$600,000, which has been donated. Plans for the erection of the building are in process of preparation.

Increased Hospital Accommodation under Consideration.—Because of the urgent need for additional hospital facilities in Baltimore, the advisability of taking over some twenty-three semirefuge buildings on the south side of the Fort McHenry reservation, now a part of U. S. Army General Hospital No. 2, which could be altered at comparatively small expense, perhaps \$100,000, and be made to fulfil the city's needs for some years to come, has been taken under consideration by the commission appointed by the mayor to study hospital conditions. It is thought that these buildings can be obtained from the government for a nominal sum and within a very short time.

Fort McHenry Hospital to Remain.—Because of the many rumors concerning the abandonment by the Army Medical Service of U. S. Army General Hospital No. 2, Fort McHenry, Col. Henry Page, the commanding officer, has recently made the announcement that there is hardly a possibility of the closing of the hospital, at least until Congress provides the soldiers at Camp Holabird with a post hospital. Discharges at the rate of about 600 a month for the last few months have reduced the number now under care in the hospital to about 1,200. Hardly more than half of these are from overseas; the remainder are patients from Camp Holabird, from the Fort McHenry detachment, and casualties from various outfits.

Personal.—Plans are being made by physicians and surgeons of Baltimore for the celebration of the seventieth birthday of Dr. William H. Welch, one of the notable group of men who have made the Johns Hopkins Medical School known throughout the world. The writings of Dr. Welch will be collected and published in three volumes, the edition being limited to the subscribers. —Dr. Lewis J. Rosenthal, Baltimore, has been appointed inspector of throats for the Baltimore City Health Department to succeed Dr. J. B. Culberson. —Dr. Benjamin M. Jaffe has been appointed health warden for the fifth ward of Baltimore. —Col. Clarence J. Manly, Medical Corps, has been ordered to U. S. Army General Hospital No. 2, Fort McHenry, to command the post in place of Col. Henry Page, who has been directed to take up his duties as commandant of U. S. Army General Hospital No. 21, Denver. —Dr. Clarence R. Dufour has been reappointed chairman of the public health committee of the Baltimore chamber of commerce.

NEBRASKA

Roentgenologists to Meet.—The Omaha Roentgen-Ray Society will hold a meeting in Omaha, March 20.

Personal.—Dr. Allan B. Anderson, Pawnee City, has retired from active practice. —The office of Dr. Frank Tornholm, Wahoo, was destroyed by fire, January 4.

NEW JERSEY

Personal.—Capt. Oscar G. Frundt, M. C., U. S. Army, Jersey City, has been awarded the Distinguished Service Cross for extraordinary heroism in action while commanding a

hospital train in Eastern Siberia, in June, 1919. The award was made on account of Captain Frundt's care and treatment of the wounded and handling of the hospital train while under fire.

Illegal Practitioners Fined.—During December, 1919, six illegal practitioners, including one physician and two osteopaths, are reported to have been arrested and fined \$200 each for practicing medicine in New Jersey without a license. They are Vincenzo D'Amico, Elizabeth; Gustave H. Heckman, osteopath, Mt. Holly; Morris Katz, Newark; Gerald Richardson, osteopath, Jersey City; A. Sassaman, New Brunswick, and Chester I. Ulmer, M.D., Gibbstown.

NEW YORK

Women to Meet.—The fourteenth annual meeting of the Women's Medical Society of New York State will be held at Hotel McAlpin, New York City, March 22; under the presidency of Dr. Elizabeth B. Thelberg, Poughkeepsie. Dr. Winifred Cullis of London, England, will be one of the speakers.

Bill to Help Brooklyn Hospital.—Governor Smith has signed the bill appropriating \$500,000 for the Creedmoor division of the Brooklyn State Hospital. This is the same item vetoed by the governor last year. He states that the plans of the hospital development commission are matured so that it is safe now to proceed with the Creedmoor construction.

Prize Offered for Poster.—The bureau of venereal disease of the New York State Department of Health offers a prize of \$100 to the person who best interprets the expression "Healthy Parents Head Happy Families," in a colored drawing that can be reproduced as a poster in public health work. Drawings must not be smaller than 12 by 18 inches. The winner will be chosen from among those whose drawings are received at the New York State Department of Health, Albany, before May 1, 1920.

Commission Recommended to Study Health Insurance.—The National Civic Federation, which has made a study of social insurance, has recommended to the state legislature the appointment of a state commission to study the relation between sickness and society. The cause and extent of sickness, prevention, treatment, and replacement of the wage loss are suggested as proper subjects for investigation. The federation's committee is opposed to compulsory health insurance in the forms in which it has been presented.

Senate Committee Discusses Nurses' Titles.—The Mullen bill which seeks legal classification of nurses was advanced to a hearing recently at which considerable opposition to the bill was voiced by physicians. Howard Townsend, representing the Hospital Conference of New York City, with a membership of about fifty hospitals, spoke in opposition to the measure. He suggested the creation of a council of advice to consist of three nurses and the same number of physicians and hospital representatives, which should be empowered to advise the state board of regents in matters affecting hospitals and the education of nurses, as a means of securing proper classification. The bill it is claimed would prevent the free use of trained attendants in the care of the sick, and this it is pointed out would be unfortunate in view of the shortage of registered nurses.

New York City

Personal.—Dr. Chester Ford Duryea has been appointed associate director of the New York Radium Institute.

Immunization Against Diphtheria in Schools.—Arrangements have been made for the administration of the Schick test and the active immunization against diphtheria of susceptible children in 100 public schools of the city.

Reminder of Necessity to Report Communicable Disease.—By order of the health commissioner, perpetual calendars, on which are printed reminders of the necessity of reporting communicable and occupational diseases, have recently been mailed to all the physicians in the city.

Functional Reeducation Work.—The first annual report of the clinic for Functional Reeducation of Disabled Soldiers, Sailors and Civilians shows that of the 1,150 patients treated the first year, about one-half were disabled working men, and the remainder disabled soldiers and sailors.

Clinic for Drug Addicts Closes.—The health department announces the closure of the clinic for the treatment of drug addicts which it has maintained at 145 Worth Street. The attendance at the clinic has fallen to fewer than 100 patients, and these will be transferred to the Riverside Hospital.

Course in Industrial Nursing Service.—The New York University School of Commerce, Accounts and Finance started February 2, a course in standardization of nursing service in industry. The course is arranged for industrial workers, welfare workers and those contemplating entering the field of industrial welfare work.

Distribution of Hospital Fund.—The United Hospital Fund, because of the shortage of funds of many of the institutions, will make a preliminary distribution of approximately \$400,000 at once. This represents about double the amount the forty-six institutions received from the fund last year. According to present plans the remainder of the fund will be disbursed about May 1.

Brooklyn Hospital Seeks Endowment Fund.—The Methodist Episcopal Hospital of Brooklyn, in its annual report, seeks an addition of \$500,000 to its endowment fund. During the past year the hospital staff has treated in all 12,072 persons. One gift during the year was a \$50,000 Liberty bond, the income from which is to be used to meet the expenses of free treatment for the poor.

Annual Report of Mount Sinai Hospital.—The report of the board of trustees of Mount Sinai Hospital, presented at the recent annual meeting, outlined the progress being made on the new buildings being erected on property adjoining the hospital. These buildings will cost \$3,250,000 instead of \$2,000,000, the amount estimated before the war. Emphasis was laid on the preparations being made for a study of the best methods of disease prevention.

Postgraduate Medical School Seeks Fund.—The board of directors of the New York Post-Graduate Medical School and Hospital have begun a drive to raise an endowment fund of \$2,000,000. The institution has purchased the property on the southwest corner of Twentieth Street and Second Avenue, which is the first step toward the enlargement of the facilities of the school, which is no longer adequate for the demands made on it. The enrolment this year is 1,692, double the attendance of last year.

NORTH CAROLINA

Chiefs of Staff Elected.—The following chiefs of staff of the Memorial City Hospital, Winston-Salem, have been appointed: chief of the medical staff, Dr. Sylvester D. Craig, Winston-Salem; chief of the surgical staff, Dr. Everett A. Lockett, Winston-Salem, and chief of the gynecologic and obstetric staff, Dr. Henry S. Lott, Winston-Salem.

Personal.—Dr. Andrew J. Crowell, Charlotte, has been appointed a member of the state board of health, succeeding Dr. Edward C. Register, deceased.—Dr. Joseph Howell Way, Waynesville, is convalescent after an attack of acute lobar pneumonia.—Dr. Andrew J. Warren, Raleigh, has been made head of the state health department of Charlotte, succeeding Dr. C. Curtis Hudson, Charlotte.

Semicentennial of Academy.—The Raleigh Academy of Medicine celebrated its fiftieth anniversary by a dinner at the Yarbboro Hotel, February 2, in honor of Drs. Wisconsin I. Royster, Richard H. Lewis and Augustus W. Knox. The after dinner program included: "Greetings from the State Society," by Dr. Carl V. Reynolds, Asheville; "A Historical Sketch of the Academy," by Dr. Hubert A. Royster, Raleigh; "Every Physician a Philanthropist," by Dr. Cyrus Thompson, Jacksonville; "Personal Reminiscences of the Founders," by Dr. Wisconsin I. Royster; "Medicine and the State," by Dr. Richard H. Lewis, and "Our Present and Our Future," by Dr. Augustus W. Knox. Tributes were also paid to Drs. G. G. Thomas, Wilmington, Lewis B. McBrayer, Sanatorium, and Charles O'H. Laughinghouse, Greenville, honored fellows of the academy.

PENNSYLVANIA

Influenza Cases.—More than 50,000 cases of influenza were reported to the state department of health between January 26 and February 28. In the epidemic of 1918 and 1919 a million cases of influenza were reported. The figures for this year's outbreak in the state were: influenza, 50,176; pneumonia, 3,271, and deaths from influenza and pneumonia, 3,068.

Baby Clinic for Ardmore.—A baby clinic was opened in Ardmore, February 10, under the financial auspices of Main Line Branch No. 1, Southeastern Pennsylvania Chapter of the American Red Cross. It is conducted in cooperation with a committee of physicians and visiting nurses. Clinics are conducted from 2 to 3 p. m., Tuesdays and Fridays, in

the Ardmore Red Cross headquarters. Later it is hoped to develop a similar clinic in Bryn Mawr.

Safety Congress.—The Pennsylvania Safety Congress for 1920 will be held in Harrisburg, March 21 to 25, inclusive, under the auspices of the Department of Labor and Industry of the Commonwealth of Pennsylvania. The congress is a continuation of the welfare and efficiency congresses held in the past, which were discontinued during the war. The topics to be discussed are those which are faced in industrial life today and will include the relation of industry to religion; the cost of industrial accidents; the cooperation of the employer and employee in safety; the future of industry; the public utility and its hazards; Americanism; women in industry; organized labor and the safety movement; the rehabilitation of the industrial crippled; health education and industry, and occupational diseases.

Philadelphia

Influenza Epidemic Over.—With comparatively few cases of influenza and pneumonia reported, the health department has removed the restrictions which were put into effect several weeks ago as measures of precaution against the spread of the disease.

Two Thousand Vaccinated.—Because of the discovery of a case of smallpox, March 2, 2,000 persons were vaccinated in West Philadelphia, March 3. Thirty-six Hog Island workers were vaccinated, March 2. The patient was an employee on a ship at Hog Island.

Measles Hospital Needed.—There have been 4,000 cases of measles since January 1, and the health officials say there is no sign of abatement. There have been at least 12,000 additional cases not reported. The department of health is considering the utilization, exclusively for measles cases, of one of the buildings of the Philadelphia Hospital for contagious diseases.

Osler Memorial Meeting.—At the stated meeting of the College of Physicians of Philadelphia, March 3, Dr. Thomas McCrae read a memoir of the late Sir William Osler; Dr. Hobart A. Hare read a paper on "Sir William Osler as Teacher and Clinician"; Dr. Charles W. Burr, one on "Sir William Osler as a Man of Letters"; Francis R. Packard one on "Sir William Osler, and the Library of the College of Physicians of Philadelphia," and Dr. George W. Norris, one on "Sir William Osler as Host to the Americans in England During the Great War."

Personal.—Dr. Charles L. Furbush, director of the department of health, who has been seriously ill with influenza, has gone to Atlantic City to recuperate.—Dr. George Victor Janvier has been appointed assistant obstetrician to the Philadelphia General Hospital.—Dr. Elmer J. Presper has been appointed medical director of the Civil Service Commission to succeed Dr. William A. Swalm, who resigned.—Dr. Neva R. Deardorff, for nearly two years assistant to the director-general of the Department of Civilian Relief of the Red Cross, has been appointed assistant to the general manager at the national headquarters.—Dr. Charles C. Hart has been elected surgeon of the Pennsylvania Commandery, Military Order of Foreign Wars, of the United States.

Woman's Medical College Campaign Fund Closed.—The extension fund campaign of the Woman's Medical College of Pennsylvania, Philadelphia, for quarter of a million dollars came to a successful close, March 11, when a joint celebration was held to mark the end of the drive and the seventieth anniversary of the founding of the college. Founder's day exercises were held in the afternoon and a final campaign dinner in the evening. The establishment of the department of preventive medicine which was one of the objectives of the campaign has been assured by the recent action of the National American Women's Suffrage Association which, at its recent convention in Chicago, voted \$30,000 as a memorial to Dr. Anna Howard Shaw.

To Check Milk Adulteration.—Drastic steps for the checking of the alleged practice of watering milk, recently brought to light through the activities of the bureau of health, are now being taken by that department. Twenty-eight prosecutions have been lodged during the past six weeks. According to John Vogelson, chief of the bureau, it is not the big milk companies that are responsible, but it is the small dealers who buy milk in cans and bottle it themselves that are to blame. Inspectors have found a large number of cases of this violation of the law in all parts of the city, but the greatest number has been reported from downtown. Many samples tested at the Phipps Institute have been found to contain butter fat below the legal standard of 3.25 per cent.

SOUTH CAROLINA

Building for Physicians.—An office building has just been completed at the corner of Brown and North streets, Greenville, by a company whose president is Dr. R. E. Houston and secretary and treasurer Dr. Samuel G. Glover. The building will be occupied by seven physicians, who are joint owners of the building.

State Association Meeting.—The annual meeting of the South Carolina State Medical Association will be held at Greenville, April 20 to 21, under the presidency of Dr. Ebenezer W. Pressly, Greenville. The address in medicine will be delivered by Dr. Edward H. Goodwin of the University of Pennsylvania, Philadelphia, and that on surgery by Dr. Stuart McGuire, Richmond, Va.

TENNESSEE

Physician's Bureau Elects Directors.—At the annual meeting of the Physician's Business Bureau of Memphis, Drs. John L. Jelks, Otis S. Warr, Hiram B. Everett, Louis Leroy, William T. Black, William Britt Burns, John C. Ayres, Louis Levy, Arthur G. Hudson, Rufus W. Hooker, Abraham L. Blecker, Frank D. Smythe, John J. Huddleston and Alfred B. DeLoach were elected directors.

Campaigns for Hospitals.—The campaign for the Jewish Hospital at Memphis, when it had raised \$400,000, was delayed temporarily on account of the prevalence of influenza. The campaign will be reopened, however, and an additional \$100,000 will be raised.—In order to raise the half million dollars for the completion of the Methodist Hospital at Memphis, now in course of construction, the conferences of Memphis, North Mississippi and Arkansas will again be asked to contribute, in addition to the gifts already made.

WISCONSIN

Physicians' Club Organized.—The Ripon Physicians' Club has been organized, with Dr. Sidney S. Hall, president, and Dr. Orvil O'Neal, secretary.

Eye and Ear Men Elect.—At the annual meeting of the Milwaukee Oto-Ophthalmic Society, February 6, Dr. Gustavus I. Hoague was elected president; Dr. Richard J. Muenzner, vice president, and Dr. John E. Guy, secretary. At the next meeting of the society, March 16, Dr. Justus Matthews, Minneapolis, will conduct a clinic.

Personal.—Dr. Otho A. Fiedler, Sheboygan, has been reappointed a member of the state board of health.—Dr. Nicholas J. Hamilton, Madison, convicted several years ago of second degree manslaughter and sentenced to seven years' imprisonment at the state prison, Waupun, has been restored to citizenship by the governor, but will not be permitted to practice medicine.—Dr. N. J. Malloy has been appointed health officer of Fond du Lac, succeeding Dr. Frank L. McGauley, resigned on account of illness.

GENERAL

American Physicians Decorated.—The king of Greece visited the American Red Cross Dispensary of Saloniki, March 7, and decorated the officers of the medical staff.

Military Surgeons to Meet.—The twenty-eighth annual meeting of the Association of Military Surgeons of the United States will be held at New Orleans, April 22 to 24, with headquarters at the Hotel Grunewald under the presidency of Col. Joseph A. Hall, M. C., N. G., Ohio.

Issue Themselves Licenses.—Just prior to a complete change in the personnel of the Oklahoma State Board of Medical Examiners recently, the outgoing board consisting of eight members, including an osteopath, are reported to have issued to themselves complimentary licenses recorded as having been based on a written examination. The record indicates that the papers of each one were graded at exactly 92 per cent.

National Tuberculosis Association Meeting.—The annual meeting of the National Tuberculosis Association will be held at the Hotel Statler, St. Louis, April 22 to 24, under the presidency of Dr. Victor C. Vaughan, Ann Arbor, Mich. Dr. Vaughan has appointed the following committee to make nominations of twelve directors to serve for a term of five years: Dr. Vincent Y. Bowditch, Boston, chairman; Drs. Edward R. Baldwin, Saranac Lake, N. Y., Walter Jarvis Barlow, Los Angeles, Hoyt E. Dearholt, Milwaukee, and Henry W. Hoagland, Colorado Springs, Colo.

Certification of Clinical Thermometers.—The fact that many clinical thermometers of faulty workmanship are offered for sale has been repeatedly discussed. An effective remedy for this evil has been found in Massachusetts, after careful tests of 10,000 thermometers by the state commissioner of weights demonstrated that 25 per cent. were defective. Under a new state law, no clinical thermometer may be offered for sale in Massachusetts unless its accuracy has been attested by the certificate and seal of the state commissioner of weights and measures. The penalty for violation of the act is a fine of \$50 for each uncertified thermometer offered for sale.

Civil Service Examination.—Application will be received until June 29 by the United States Civil Service Commission for an open competitive examination for bacteriologist and junior bacteriologist in the United States Public Health Service, the salary for bacteriologist ranging from \$130 to \$180 a month; for associate bacteriologist, from \$90 to \$130 a month; for assistant bacteriologist, from \$70 to \$90 a month; for junior bacteriologist, \$70 a month, and for junior bacteriologist part time, at \$30 to \$50 a month. Appointees will be allowed subsistence and one room, or \$15 or \$20 for commutation and quarters, according to grade of station.

Wood Alcohol Poisoning.—The National Committee on the Prevention of Blindness sent recently a request for authoritative information to the health officers of each state, the health officers of 100 of the largest cities, state commissions for the blind, associations for the blind, hospitals, and to prosecuting attorneys asking for the number of deaths and the cases of total or partial blindness occurring since Aug. 1, 1919, from alcohol, wood alcohol "whisky," denatured alcohol and forms of wood alcohol poison unknown. Up to date answers have been received from about one third of the questionnaires sent out:

No. of deaths from wood alcohol poisoning	145
Wood alcohol straight	10
Wood alcohol "whisky"	61
Denatured alcohol	4
Form of wood alcohol poison unknown	68
Florida toilet water	1
Extracts	1

Bequests and Donations.—The following bequests and donations have recently been announced:

Jewish Hospital, Philadelphia, \$10,000 for the endowment of a room in memory of himself and wife, Mt. Sinai Hospital, \$3,000, and Jewish Sanatorium, Eaglesville, Pa., \$1,000 by the will of Herman Prager.

St. Barnabas Hospital, Newark, N. J., \$3,000 by the will of Miss A. A. Westervelt.

Julia F. Burnham Hospital, Champaign, Ill., a gift of \$75,000 by Mrs. Newton M. Harris, with an additional \$25,000 conditional on the subscription of a like amount by the community.

Sanatorium for blind babies, \$2,500; Harvard Dental School, \$500 by the will of Mrs. Louisa A. Beal.

Harrisburg, Pa., Hospital, \$25,000 by the will of Mrs. Andrew J. Duill.

St. Luke's Hospital, Bethlehem, Pa., \$5,000 to endow a bed to be known as the Josiah Bachmann Free Bed, by the will of Josiah Bachmann.

Bryn Mawr, Pa., Hospital, \$50,000 by the will of Mrs. Lois Buchanan Cassatt.

Miami County, Ind., Hospital, Peru, \$1,000 for the endowment fund by the will of Ner Black.

Physicians Needed in Orient.—The Interchurch World Movement (45 West Eighteenth Street, New York City) has issued an appeal for physicians for five years' service in the near and far eastern countries. The appeal is directed chiefly to recent graduates and to physicians discharged from military service who have not yet become reestablished in practice. In addition to general practitioners, specialists in pathology, neurology and psychiatry are urgently needed for service in Turkey, Syria, Palestine, Persia, Siam, Indo-China, Malaysia, Philippine Islands, India, Africa, China, and Japan. There are places for more than 600 physicians, men and women. Married physicians who enlist for five years will be provided with a home and an annual salary equivalent to \$3,000 in United States currency. Single physicians will be allowed an annual salary of \$2,000. All traveling expenses will be paid. A grant from the Rockefeller Foundation for a course in postgraduate work in America may be available to those who give five years' service in China.

The Influenza Epidemic.—During the week ending February 21, the incidence of epidemic influenza declined definitely in thirty-seven of forty states from which reports were received by the Public Health Service. Increases were recorded in Georgia, Oregon and Vermont, and only relatively small decreases were noted in Maine, New York and Louisiana. Taking the forty-six large cities as a whole the peak of mortality was reached in the week ending February 14, when there was an excess of 1,322 in the annual mor-

tality rate per hundred thousand of population as compared to the norm for the corresponding week of the median period 1910-1916. In the weeks immediately preceding and following this the excess rates were 1,241 and 853, respectively. At the height of the epidemic of 1918, the excess annual mortality rate in the three peak weeks was 4,592, 4,695 and 3,332 per hundred thousand. A statistical comparison of the epidemics of 1920 and 1918 reveals a striking constancy in the ratios of the excess mortality rates. Although the peak rates for the different cities vary from 5 to 152 per cent. as compared to those for 1918, the mortality chargeable to the present epidemic is so far under 30 per cent. of that in 1918. In five cities—St. Louis, Kansas City, Detroit, Milwaukee and Minneapolis—the peak rate in this epidemic has exceeded that in 1918, while the excess of mortality in Albany, N. Y., Baltimore, Boston, Cleveland, Richmond, Va., San Francisco and New Orleans, was less than 20 per cent. of that recorded in the first epidemic, New Orleans having the lowest ratio, 5 per cent. There was a definite geographic movement of the epidemic, which developed in two well separated areas, one along the Great Lakes and the other in the Middle Atlantic region represented by New York City and Washington, D. C.

Medicines and Hospital Supplies for Sale by the Government.—The Surplus Property Division, Office of the Quartermaster General of the Army, offers for sale to all classes of buyers a quantity of surplus drugs and medical supplies on which fixed prices have been established. The present offer will be in effect from March 5 to April 5, 1920. No official forms are required; orders may be made by letter or telegram. Full shipping instructions should accompany all orders. No deposit will be necessary on orders amounting to less than \$1,000.

A list of articles for sale contains the prices and minimum quantities of drugs, of which the following are a few examples: boric acid tablets (324 mg.), 500 for \$0.60; ammonium chlorid, \$0.20 a pound; silver nitrate crystals, \$0.76 an ounce; barbital tablets (324 mg.), 100 for \$1.50; caffeine citrate tablets (0.65 mg.), 500 for \$3.30; chloral hydrate, \$0.06 an ounce; chloroform (one-fourth pound tins), \$0.25 a pound; collodium, \$0.02 an ounce; iodine, \$0.23 an ounce; nitroglycerin tablets (65 mg.), 20 for \$0.10; phenol (5 pound tins), \$0.16 a pound; aromatic spirit of ammonia (one-half pound bottle), \$0.65 per pound; strychnin sulphate (1 mg. hyp. tablets), 20 for \$0.05. Also listed are surgical instruments, rubber aprons, operating tables, litters, bandages and crape paper.

Further information may be obtained from and orders may be sent to the "Zone Supply Officer" at any of the following addresses: Army Supply Base, Boston; 461 Eighth Avenue, New York City; Twenty-First Street and Oregon Avenue, Philadelphia; Coca Cola Building, Baltimore; Transportation Building, Atlanta, Ga.; Army Building, Fifteenth and Dodge Streets, Omaha; Fort Mason, San Francisco; Seventeenth and F Streets N.W., Washington, D. C.; Newport News, Va.; Jeffersonville, Ind.; 1819 West Thirty-Ninth Street, Chicago; Second and Arsenal Streets, St. Louis; Audubon Building, New Orleans; San Antonio, Texas; New Cumberland, Pa.; Columbus, Ohio, or to the Surplus Property Division, Medical and Hospital Section, Munitions Building, Washington, D. C.

FOREIGN

Hospital Shelled by Turks.—An Associated Press telegram of February 29 states that the American Hospital at Marasch was shelled by Turkish nationalists, January 22 and 23.

Edinburgh College of Surgeons Admits Women.—At an extraordinary meeting of the College of Surgeons of Edinburgh held, March 3, it was resolved that women should be admitted to fellowship in the college.

Coordination Between Hospitals in France.—Dr. Tuffier of Paris has been charged with the permanent task of technical inspection and supervision of the public health service hospitals of the country, to arrange for effectual coordination.

Council on Natality.—The French authorities have appointed a Conseil supérieur de la natalité in the public health service. Our exchanges comment on the fact that only three physicians are included in the thirty members of the council.

Chemical Companies Merge.—Plans are well under way for the amalgamation of two of the largest chemical companies in Great Britain, Brunner Mond & Co., with a capital of more than \$48,665,000 and the Castner Kellner Alkali Co., with a subscribed capital of \$4,866,500.

Tax on Roentgen-Ray Plates.—The *Archives d'électricité* of recent date brings a vigorous protest by Dr. de Courmelles against the "iniquity" of the present luxury tax in France of 10 per cent. on the plates used in radiography. "As if," he exclaims, "it is a luxury to have a diagnosis cleared up by radiographic examination."

Night Medical Service at Paris.—The night medical service in Paris has been reorganized and thirty physicians under 30, or 35 if they have served in the war, are to be appointed to serve in turn, with an automobile at their disposal. The term of service is for three years, and the salary is 3,000 francs. This amounts to 50 francs for each night of service, the number falling to each physician being about sixty. Provision is also made for five substitutes. The service is connected with the police department.

Medical Cooperative Society.—The physicians of Brussels, Antwerp, and Liège have founded in each of these cities a cooperative store for the benefit of physicians, pharmacists, veterinarians, midwives, and widows of members of these professions, and also docteurs en sciences. The society at Liège is affiliated with the Association contre la vie chère at Antwerp, and the Coopérative médicale at Brussels, and the store will carry samples of goods to be ordered, besides a large stock of canned goods, cigars, etc. The shares are 100 francs each and no one is allowed to buy more than ten shares. The Prévoyance médicale, of Liège, as it is called, started with 183 shareholders and the store opened in January.

Deaths Abroad.—Sir Thomas Peter Anderson Stuart, University of Edinburgh, 1882; D.Sc., University of Durham, 1911; LL.D., University of Edinburgh, 1900; aged 63; professor of physiology and dean of the medical faculty of the University of Sydney, New South Wales; who organized the expedition of the Royal Society of London, to Funafuti, an island of the Ellice Group in the Pacific, which by boring to a depth of 1,000 feet into coral rock secured confirmation of the Darwinian theory of reef formation; died, March 3. —Dr. Knud Poulsen, a leading physician in Denmark, succumbed to fulminating infection after droplets from a streptococcus sore throat had been coughed in his face, aged 48. —Dr. Braun, inspector-general of the public health service in Morocco, and recently appointed director of the same service at Strasbourg.

The Nursing Profession in Europe.—With the assistance of the American Red Cross, the first school for nurses in Czecho-Slovakia has been established at Prague under the direction of American nurses. It is expected that within three years the training school will be in charge of Czecho-Slovakian nurses, for two native women have been sent to the Massachusetts General Hospital to prepare for this eventuality. In Poland there are now over fifty nurses' aides in training at various hospitals under the direction of the American Red Cross and more than 130 volunteers are receiving preliminary instruction. The need for nurses is felt keenly in Eastern Europe, for fighting is still going on and thousands of sick and hungry refugees are returning from their exile in Russia, bringing with them typhus fever, cholera and dysentery.

Memorial Tributes to Baccelli.—A national committee in Italy has charge of the task of honoring the memory of Guido Baccelli, and on the fourth anniversary of his death a notable meeting was held in the capitol where a bust of Baccelli was unveiled and his important and pioneer work as physician, medical teacher and research worker, and as statesman was extolled by leading men of the nation. It is the third time that a special celebration in his honor has been held in the capitol—two of them during his lifetime—an unprecedented tribute. A tablet was also placed on his late residence, and a special public meeting was planned in the Baths of Caracalla, among the excavations of ancient Rome which Baccelli inaugurated and superintended. To him are due also the laws relating to the draining of the marshes around Rome; he inaugurated also the administration of heroic drugs by the vein.

Red Cross Items.—The first meeting of the General Council of the League of Red Cross Societies was held in Geneva, Switzerland, March 2 to 10. Two main topics were discussed at the meeting. The first related to the improvement of public health and the prevention of disease according to the program outlined at the Cannes meeting in April, 1919, and the second was the consideration of the program of service in peace time, the most effective means of extending the membership and resources of the Red Cross. In addition to these general topics the thirty societies which are members of the league supplied samples of posters, pamphlets, moving picture films,

and other material used during or since the war by the national societies. —The National Red Cross Society of Czecho-Slovakia and Uruguay have joined the League of Red Cross Societies. —Dr. Octave Monod of the Pasteur Institute, Paris, has been appointed assistant chief of the department of tuberculosis. —Mr. C. R. Hewitt, formerly librarian of the Royal Society of Medicine, London, has been made librarian of the league.

Scientific Publications in Germany.—The *Münchener medizinische Wochenschrift* quotes Prof. von Harnack, the librarian, speaking at a recent convocation of the University of Berlin on the plight of German science. He explains it as follows: "(1) Because we are unable to buy any more foreign books and periodicals; the library with its present resources can subscribe only to 170 foreign periodicals instead of 2,300. The library had appropriated 112,000 marks to purchase works that had been published in other countries during the war, but it would take over a million marks to buy these works now. (2) Our scientific journals in Germany are in a most precarious condition (auf dem Aussterbeetat) as the publishers are no longer able to take the risks. (3) No more scientific monographs can be published as the scientific academies are no longer able to subsidize them. (4) The books already on hand in Germany, especially the great collected works on scientific subjects, are flowing out of the country in great numbers. Even the textbooks, when the editions dating from cheaper times are exhausted, will become unbelievably expensive."

LATIN AMERICA

Lethargic Encephalitis in Peru.—The Lima Academy of Medicine states that several cases of lethargic encephalitis have occurred in Lima.

Branch of American College of Surgeons in Peru.—During the visit of Drs. Mayo and Martin to Lima, Peru, there was organized in that city a branch of the American College of Surgeons.

Death of Dr. Coyula.—Dr. Luis Coyula, mayor of the city of Mexico, died suddenly on March 3 of heart disease. Dr. Coyula was a former professor of physiology in the school of medicine.

Medical Expert Wanted in Paraguay.—Among various experts whose services are desired by the government of Paraguay, one should be an expert in tropical diseases. The minister in Washington is in charge of the matter.

Influenza in Mexico.—The epidemic of influenza in Mexico is abating rapidly. All churches, theaters and schools have been reopened. The official reports show that there have only been sixty-six deaths from the disease recently.

Brazilian Hospital Items.—Dr. Graciano Feliciano, present head of the public health service of Bahia, has been appointed assistant director of the Central Military Hospital. —The new military hospital at S. Paulo will soon be open, with Lieut.-Col. Brenno Moniz as its first director.

New Asylum for Infants in Santo Domingo.—An infant welfare association under the name of *Gota de Leche* has recently been established in Santo Domingo. At its headquarters it has accommodations for twelve children, in addition to a medical dispensary, milk station, and a public bath department.

Enforcement of Patent Medicine Regulation.—An executive resolution was promulgated in Havana, February 11, by which the following articles of the pharmacy regulations of 1913, enforcement of which had suspended were finally put into effect:

ART. 46.—Foreign patent medicines must be registered with the Bureau of Health by agents or importers, and their circulation in the country shall be permitted only upon fulfillment of the following conditions: (a) The labels must name the constituents to which the patented article owes its medicinal property; (b) the labels must also state the name of the manufacturing druggist or company in the country of origin.

ART. 47.—No patent medicine shall be put on sale before its registration with the Bureau of Health. A certificate of registration will be issued by the said bureau within three days from date of application.

Gold Medal Presented to Dr. Pérez Aranibar.—The Sociedad de Beneficencia Pública of Lima, Peru, recently presented its former director, Dr. A. Pérez Aranibar, with a jeweled gold medal in token of appreciation of his indefatigable and efficient management of this official system of organized charities. In commenting on the event, the *Crónica Médica* remarks that the tribute is simple justice, as he took a very

active part in carrying through a number of works and improvements of a medicosocial nature while he was in office during 1917 and 1918.

Changes in the "Brazil-Medico."—Our Rio de Janeiro exchange enters on 1920 and its thirty-fourth volume with a change of management, the former general manager for twenty-six years, Dr. Bulhoes Carvalho, having been obliged to resign his connection with the journal as he has been appointed director of the state department of statistics. The editor in chief of the *Brazil-Medico*, Dr. Azevedo Sodré, remains in charge and his two sons have assumed the management. They have already enlarged the journal and introduced an extensive news department and current literature department, following the style of *THE JOURNAL* to some extent. The management announces further that arrangements have been made for special correspondence from four of the principal cities of Brazil, and from Paris, Berlin and New York.

Government Services

Base Hospital Receives Appropriation

Seventy-five thousand dollars has been appropriated from the funds of the construction division of the War Department for the improvement of the base hospital at Fort Sam Houston.

Hospital Discontinued

The Surgeon-General's recommendation to discontinue U. S. General Hospital 43, Hampton, Va., has been approved and the director of real estate service has been instructed to cancel the lease and return the property to the board of managers of the National Home for Disabled Volunteer Soldiers.

Medical Veterans of the World War

Col. Frederick F. Russell, M. C., U. S. Army, secretary of the Medical Veterans of the World War, states that during February, 169 new members joined, making a total membership of 2,711 divided as follows:

Medical Corps, U. S. Army.....	1,245
Medical Corps, U. S. Navy.....	51
Medical Corps, U. S. P. H. S.....	62
Contract Surgeons, U. S. Army.....	88
Acting Assistant Surgeons, U. S. P. H. S.....	47
Members Local Board.....	527
Members Examiner, Local Board.....	183
Members Medical Advisory Board.....	508

Bill to Purchase Land of Army Hospital at Azalea, N. C.

Senator Wadsworth, chairman of the Committee on Military Affairs, introduced a bill, March 6, authorizing the payment of \$55,000 for the purchase of land on which the army hospital at Azalea, North Carolina, is located. The hospital buildings at this site cost the government \$2,600,000, but no arrangement has ever been made for the purchase of the land on which the buildings are located. Secretary of War Baker wishes to use this camp as a permanent one, and has asked Congress for authorization to purchase the land, which consists of 360 acres. It is located at an altitude of 2,000 feet and is well situated for the treatment of army tuberculosis patients. The hospital has a capacity of 1,300 beds and there are 900 patients there at present.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Foreign Correspondence

LONDON Feb. 13, 1920.

The Study and Treatment of Mental Disorders in Early Stages

In a joint letter to the *Times*, Allbutt, Barlow, Savage, Mott, Armstrong-Jones and others draw attention to the urgent need of reform in the methods of dealing with mental disorders. In 1918, the Medico-Psychological Association of Great Britain and Ireland, after considering the amendment of the existing lunacy laws, reported that there are few facilities for patients threatened with mental breakdown to obtain skilled treatment until they are certified as insane and placed in asylums, whereas the early symptoms often occur long before certification is possible; that, owing to delay in treatment, the most valuable time for securing early recovery is lost; that the public, being alive to the material and moral damage which certification often inflicts on the patient and his relatives, refuses to resort to it even when it has become possible, still further postponing efficient treatment; that the subsequent course often shows that certification might have been avoided had there been facilities for treatment under other conditions, and that many physicians, having had no opportunity of gaining knowledge of the manifestations and treatment of mental disorders in their early stages, fail to recognize the seriousness of the condition and are, further, deterred by the necessity of certifying the patient from advising suitable treatment. The signatories of the letter endorse the proposals made by the association for the provision of treatment in the early and curable stages without certification, the provision of psychiatric clinics, especially in connection with large hospitals and medical schools, and the extension of the system of voluntary admission (which now obtains in respect of licensed houses and registered hospitals for the insane). Of these proposals, the establishment of psychiatric clinics is considered the most important. In regard to these, this country is deplorably backward compared with other European countries and the United States.

Vocal Therapy

The therapeutic value of singing, both by causing full expansion of the lungs and by its invigorating effect on mind and body, is not sufficiently appreciated. A "Vocal Therapy Fund" has been formed with a committee containing several well known leaders of the profession, including Mott, Dundas Grant and Martin Flack. In appealing for funds, the committee points out that the work is partly curative, consisting of individual training, under medical supervision, of men suffering, through shock and strain, from stammering, aphonia or mutism, and partly restorative, by instruction in choral singing, taking advantage of the well known power of song to cure ailments affecting speech and respiration. Trained choirs have been organized which give concerts both in and out of hospitals, and "song centers" have been started at general and special hospitals and hostel centers in London and the provinces. It is thought that the treatment would be especially applicable to the many thousands of medically unfit men discharged from the military hospitals who are unable to return to the full use and enjoyment of life.

A Diploma in Medical Radiology and Electrolgy

The increasing importance of electricity and the roentgen rays in therapeutics is being recognized in several ways. A movement is on foot to give full staff rank to the medical officers in charge of the departments devoted to these agents at the hospitals. The University of Cambridge has instituted a diploma in medical radiology and electrolgy, the first examination for which will be held next July. A course of instruction in physics and electrotechnics was begun at Cambridge in January, and one on radiology will begin in April. Most of the leading workers in these subjects are taking part in the teaching.

Australasian Medical Congress

After a lapse of more than six and one-half years, the Australasian Medical Congress will again meet. The eleventh session will be held at Brisbane from August 23 to 28, under the presidency of Hon. W. F. Taylor, M.D. A resolution of the congress that future meetings shall be meetings of the branches of the British Medical Association has been declared informal, but opportunity will be given for a formal decision as to whether the functions of the congress and its

assets shall be taken over by the British Medical Association. Preparations for the Brisbane session were begun in July, 1914, with the intention of holding it in 1917, but the outbreak of war postponed the meeting. The work of the congress has been divided into eleven sections, of which one is on Naval and Military Medicine and Surgery, to which a large contribution is expected from returned army and navy medical officers.

Flying Laboratories

The Cairo to Cape aeroplane flight across the whole of Africa from north to south, in which Dr. Chalmers Mitchell, the well known zoologist, is carried for purposes of scientific observation, has led Sir Ronald Ross to suggest in the *Times* that the time has come when it is feasible to consider the possibility of using aeroplanes for the medical exploration of Africa and other dark countries. He cannot say how far the suggestion would be practicable, especially in countries largely covered with bush and not at present possessing cleared landing places. But such an exploration would be of great use. He suggests that each exploring plane should carry not only a pathologist and a small portable laboratory, but also one or more clinicians, for the purpose of relieving the sickness of the poor natives who otherwise might never hope for the benefits of medical science. Research would, of course, go hand in hand with clinical work. It would be necessary ultimately to establish base hospitals and laboratories at the main aerodromes along the route.

Prohibition of the Importation of Japanese Shaving Brushes

In view of the fact that cases of anthrax have resulted from the use of shaving brushes manufactured in Japan, as reported in previous letters to *THE JOURNAL*, the government has prohibited the importation of shaving brushes from that country.

Physicians Among the German War Criminals

The list of German war criminals whose surrender is demanded by Great Britain contains the names of several commanders of submarines who sunk hospital ships. The general principle that has been followed is not that of demanding men who carried out any system, however inhuman and contrary to the rules of civilized warfare, under superior orders, but of demanding only those who, in addition, committed atrocities on their own account. For offenses against prisoners of war in German camps, eighteen physicians are wanted.

PARIS

Feb. 5, 1920.

Renewed Efforts to Increase the Birth Rate in France

J.-L. Breton, the newly appointed minister of social hygiene, social assistance and social prevision, recently submitted to the president of the republic for his signature a proposed decree providing for the establishment of a Conseil supérieur de la natalité, whose duty it shall be to investigate and promote all measures that may serve to combat the decrease in population, to increase the birth rate, to aid child welfare, and to give added protection to large families. In giving the reasons that moved him to propose this decree, the minister refers to the many serious disadvantages that result from the low birth rate in France, especially in view of the fact that the war has deprived France of at least 2,000,000 young men. This serious situation in France, he stated, had already been the subject of much study. It has long been recognized that it could not be attributed to a single cause, but that a multiplicity of causes was involved. Likewise, in order to combat the situation, a single remedy would not suffice, but that a series of remedies must be applied, some of a moral, and some of a material and economic nature. The Conseil supérieur de la natalité consists of thirty members, among whom are Dr. Pinard, member of the chamber of deputies, and formerly professor of the Faculté de Médecine de Paris; Dr. Jacques Bertillon, president of the Alliance nationale pour l'accroissement de la population, and Dr. Charles Richet, professor of the Faculté de Médecine de Paris. Professors Richet and Pinard have been appointed vice presidents of the council.

Duties of Pharmacists in the Matter of First Aid

There is no law compelling a pharmacist to dress the wounds of any person. However, from a recent decision of the Cour de Cassation, it would appear that a pharmacist who is summoned by the police cannot repudiate the summons thus served. The case in question was that of a pharmacist of Grenoble, who was summoned one night to

dress a slight wound that a young man had received. The pharmacist had refused to furnish the service required. The police court reached the decision that, the benign character of the wound being known, there was no reason why the pharmacist should not have dressed it. The pharmacist was found guilty and sentenced in consequence of his neglect. When the case came before the Cour de Cassation (the supreme court of appeal) the pharmacist pleaded the fact that, not being a physician, he could not legally be required to perform the service in question. The Cour de Cassation, however, rejected his appeal, holding that a single act of intervention in the treatment of the wound would not have constituted an illegal act in the exercise of the rights of the medical profession. This decision has been severely criticized by lawyers who are experts in medicolegal and pharmaceutical matters of this nature. One such expert compares the case of the pharmacist of Grenoble to that of another pharmacist of the same region who was sentenced, a few years ago, for having dressed a wound, which was also of benign character—at least, to all appearances. It is true, in the second case, the patient died of tetanus a few weeks after the dressing was applied by the pharmacist. The points of resemblance in the two cases show that it is difficult for a judge to base a verdict on the supposedly benign character of the wound.

The Use of Ether in the Treatment of External Infections

For several years Dr. C. Souligoux, surgeon to the hospital of Beaujon, has been employing ether as a routine in the treatment of external infections (wounds, compound fractures, lymphangitis, erysipelas) and of peritoneal infections. The treatment of generalized peritonitis by ether lavage of the peritoneum has even come into general use. In view of this fact it may be of interest to review the circumstances under which this method of treatment came into use. In 1892, a patient who had been run over by a heavily loaded dray was admitted to the Hôpital de la Pitié. He was treated in the service of Professor Le Fort. Both legs of the patient were badly crushed. There were comminutive fractures, complicated by wounds filled with the mud of the street, and it seemed useless to hope for the recovery of the patient unless both legs were amputated at once. The patient refused point blank to have the amputation done, and would not listen to reason. Souligoux, therefore, proceeded to cleanse the wounds, using for this purpose alcohol and ether. A plaster cast was applied to each leg. To the profound surprise of the surgeon, the patient developed no infection and recovered. Souligoux concluded that this unhopd-for success was due to the fact that the ether, by rapid volatilization at body temperature, had disinfected the wound throughout, in that it had penetrated to the uttermost recesses. This, then, was the beginning of the ether treatment, which has been regularly used by Souligoux ever since.

Lethargic Encephalitis

Dr. A. Netter, agrégé professor of the Faculté de médecine de Paris and physician to the hospitals, recently called attention to the reappearance of lethargic encephalitis, a slight epidemic of which in May, 1918, he had already reported. The disease exists at present in epidemic form at Lille and in the vicinity. At Paris, and in the suburbs of Paris, there are more than 100 cases, scattered through various quarters of the city. The disease is characterized mainly by three symptoms: somnolence, paralysis of the cranial nerves (especially the oculomotors), and a more or less accentuated febrile state.

Dr. Achard, professor of the Faculté de médecine de Paris, likewise has had an opportunity of observing several cases of lethargic encephalitis, and he has called attention to certain interesting manifestations that accompany the disease, more especially the possibility of the existence of a meningeal reaction, while two of his patients presented a marked lymphocytosis. These findings have practical diagnostic value, as it is evident that a diagnosis of lethargic encephalitis must not be excluded merely because of a meningeal reaction or a lymphocytosis; nor should one be led into making a diagnosis of tuberculous meningitis, which one might otherwise be tempted to do, at times. Achard also reports the coexistence of a recurrence of lethargic encephalitis with a second attack of influenza. The reports of lethargic encephalitis accompanying influenza are still a subject of much controversy. Without wishing to go so far as to utter an opinion on the question as to whether it is the influenza virus that produces the pathologic changes in the brain or whether these are due to a superadded virus, Achard is nevertheless convinced that a relation exists between

lethargic encephalitis and influenza. Moreover, it had been pointed out by Netter in 1918 that a coincidence, at least, existed, in that the conditions favorable to the expansion of the two diseases appeared analogous.

Dr. Pierre Marie, professor of the Faculté de médecine de Paris, states, in this connection, that when one encounters an affection with soporose manifestations, associated with cephalalgia and ocular troubles and accompanied by a pronounced meningeal reaction, one should suspect, first, either tuberculous meningitis, or—in adults more especially—syphilitic meningitis, which is of frequent occurrence and is accompanied by manifestations analogous to those of lethargic encephalitis. Marie added that he had known of distinguished physicians failing to make a proper differential diagnosis under such circumstances, and that he feared such errors would become more frequent now that lethargic encephalitis was so much in vogue.

BELGIUM LIÈGE, Feb. 20, 1920.

The Cancer Problem

The campaign that has been undertaken in this country to stay the progress of cancer continues to exert a favorable influence on medical studies calculated to throw light on the etiology and the therapeutics of this disease. The cancer commission has announced to the medical profession that, owing to the funds placed at its disposal by the government, it has in its hands the bestowal, annually, of several prizes to be given as awards to the authors of the best works on various questions pertaining to the knowledge of cancerous affections. Aside from questions that can be effectively taken up only in special laboratories, there are many others that rest on observation, pure and simple, and to which, therefore, any observing practitioner can make a useful contribution. To the second class belong such questions as: (1) the geographic or regional distribution of cancer in our country; (2) the conditions favoring the genesis and the further development of cancer; (3) questions of heredity, contagion and epidemicity; (4) the critical examination of various forms of treatment recommended against cancer, and (5) the duration of so-called "cures." The purpose of the commission is not only to favor, to the extent of its resources, every investigation of the true nature of cancer, but also to collect and coordinate the vast amount of authentic but scattered information in regard to the ravages caused in Belgium by cancerous affections and with respect to the best means of combating them. To accomplish these ends, the commission has issued an urgent appeal to the Belgian medical profession, as a whole, to take an active part in the campaign that has been launched.

The Coagulation of Blood in the Serous Cavities

The question of the coagulation of blood discharged into the serous cavities, and especially into the pleural cavity, gave rise to numerous investigations and much discussion during the progress of the war just closed. Delrez (*Archives médicales belges*), Stassen and Voncken (*Laboratoria*) were agreed that all blood effusions coagulated in a normal manner on account of a slight abrasion of the serous membrane, the wounding of which constituted the first cause of the coagulation, whereas Grégoire and Courcoux (*Coll. Horizon*) thought that blood extravasated into the serous cavities lost the property of coagulating and acquired, on the contrary, anticoagulating properties. At a recent meeting of the Société Belge de Biologie, M. Gratia brought up the question again. He says that ordinarily an aspirated traumatic pleural effusion remains in a fluid state. He maintains that the effusion consists of defibrinated blood which no longer contains any of the elements of coagulation; no fibrinogen, no cytozym, no thrombogen, no thrombin. It contains, however, large quantities of antithrombin, and when heated at a temperature of 56 C. it possesses the property of flocculating the fibrinogen. When an effusion is coagulable in vitro it is either because it contains blood freshly discharged by the wound as the result of an evacuative puncture that was carried too far or because an exudate has been added which did not coagulate in the cavity owing to the protection of the endothelium of the serosa which has cicatrized in the meantime.

Medical Printing

Owing to the annoyances that constantly arise in connection with the ever increasing scarcity of labor and the difficulties of production in general, the Belgian medical federation has formed an incorporated joint-stock company, with a capital of 400,000 francs, for the purpose of founding a medical and

scientific printing establishment, with a view of facilitating the work of printing and publishing for physicians and pharmacists. One of our medical journals, the *Scalpel*, is already being published by the corporation. The corporation expects to provide not only for the editing and publishing of medical works, but will also conduct, in connection, a stationery department, a book-store and a bookbinding department. This innovation is only the natural outgrowth of a movement toward medical reciprocity which is manifesting itself in all the large cities of the country. Since the signing of the armistice, in order to combat the high cost of living, Brussels, Antwerp and Liège have established cooperative societies, which handle not only groceries and foodstuffs, but also clothing and other articles of prime necessity. These cooperative societies are beginning to get into full working order.

Cancer of the Prostate Treated by Radiotherapy

Dr. Le Clerc Dandoy has communicated to the Société belge d'urologie his observations of a case of cancer of the prostate, in which radium exerted a favorable effect. The rarity of the case makes it worthy of mention. Three exposures to the roentgen ray and six applications of radium, by the prostatic urethra and by the rectum as well, all within three hours, was the technic employed. The symptoms improved rapidly. The pain which was unbearable subsided almost completely. The gradual disappearance of the tumor could be followed by rectal palpation. Strange to relate, running parallel with the breaking up of the tumor, the general health of the patient was much affected. Fever, oliguria and delirium were present, but gradually disappeared. This parallelism between the regression of the cancerous tissue and the appearance of general symptoms was maintained up to the end of the treatment.

A National Congress for the Study of Questions Pertaining to Disabled Soldiers and Sailors

Now that the normal affairs of life have been completely resumed, and now that the situation of all those who returned, after the war, to their abandoned firesides has been stabilized, the solution of all questions pertaining to disabled soldiers and sailors should be brought about with as little delay as possible. All those who had been called on to devote their time and energies to these questions were recently summoned by the minister of war to meet together in a national congress, to which the Association des Invalides was also asked to send delegates. The reports presented to the congress emphasized the necessity of close collaboration between the surgeon, the physiotherapist, the reeducator and the prosthetist. The value of collaboration between various specialists had been brought out by the war in all branches of medicine. In the case of disabled soldiers and sailors, more than anywhere else, collaboration was needed; in fact, it was indispensable. Unity of treatment should be everywhere present, from the time the men are injured, right up to the time when, provided with such prosthetic apparatus as they may need, they leave the school of reeducation, where they have learned to make ready use of prosthetic appliances and where they have been trained, if necessary, for a trade or profession. Dr. Hendrix gave an outline of the great work that had been accomplished by the Belgian Army Medical Corps at the famous center Bonsecours-lez-Rouen, and also described the newly established center at Woluwe (Brussels) to which all the services formerly at Bonsecours have been transferred. The services at Bonsecours were known to all the allies, and they served as models for all who wished to familiarize themselves with the organization and practical workings of reeducation centers.

In this connection a new question has arisen. Shall the state as such continue to manufacture the prosthetic appliances for the crippled and disabled? Or shall production be decentralized and private industries be permitted to develop and manufacture orthopedic equipment? This question, being one of great present interest, provoked a lively discussion, and it did not take the members of the congress long to reach a common agreement as to the desiderata required in the premises. It was agreed that, in order to assure every guaranty of safety and quality, the manufacture of prosthetic apparatus for the use of disabled men should be entrusted solely to such manufacturers as would accept medical direction and control. It was further agreed that the state could best secure a full and complete guaranty as to quality of workmanship by turning over to the Oeuvre nationale des invalides, and to it alone, the necessary funds for the equipment with, and for the upkeep and the renewal of prosthetic appliances, etc., required by disabled soldiers and sailors. The manner of using such funds should be left entirely to the

Oeuvre nationale des invalides, which would act through a mixed commission appointed to study into the details of manufacture of the required equipment and into the best methods of regulating the matter of upkeep and renewal of apparatus. This commission would be composed of army experts, members of the Belgian Red Cross, delegates of the Belgian orthopedic industry, and representatives of the disabled soldiers and sailors. In order to furnish a concrete exhibit of the progress that is being made daily in the manufacture of prosthetic appliances, it was proposed that a museum be established which should contain samples of all prosthetic appliances used by disabled soldiers and sailors. The congress also took up the study of certain financial questions pertaining to the disabled men. It considered especially the matter of government aid, which has been proposed, to assist them in the construction of simple dwellings, in the securing of small garden tracts, the opening of small shops and the purchasing of equipment in line with their profession.

MEXICO CITY

Feb. 28, 1920.

The Academy of Medicine

During the recent sessions of this association the following subjects have been discussed: Dr. Godoy Alvarez read an interesting paper on the symptomatology, and the medical and surgical treatment of the common duct obstructions, which was very widely discussed and served to bring to the fore again the virtues of the springs of Tehuacan in lithiasis. Dr. B. Vasconcelos reported a case of probable syphilitic reinfection following treatment with intravenous injections of arsphenamin and intramuscular injections of mercury. The case was in a young man who about the middle of 1917 had an indurated chancre, the syphilitic character of which was demonstrated by the presence of spirochetes. The patient had no secondary manifestations and received six injections of arsphenamin and about ten of mercurial oil. In December, 1919, after exposing himself again and after an incubation period estimated at fourteen days, he presented a new chancre at a different site on the penis, without any bubo. The spirochete was again isolated from this chancre and the Wassermann reaction was very strongly positive in the blood serum. It was not possible to persuade the patient to have a Wassermann made between the appearance of the first and second chancre; so it is not known whether the reaction was constantly negative, as should be the case before a patient is pronounced definitely cured. For this reason and because of absence of a bubo (which was lacking also in the first instance) it cannot be stated with certainty that it is one more case of reinfection to add to the large number collected by Emery in his recent pamphlet, "Traitement abortif de la syphilis" (Paris, Vigot Frères, 1914), and those observed more recently, such as that of Schamberg (described in THE JOURNAL). Another communication on syphilography condemns with strong reasons, at least provisionally, the use of Query's serum, which is considered as lacking sufficient scientific basis and should be mistrusted because of the silence maintained about it by all well-known French syphilologists.

Child Welfare Congress

Owing to the initiative of Sr. Palavicini, editor of a local newspaper, the first Mexican child welfare congress is to be held in September, 1920. Not only physicians but all persons interested in social matters are invited to participate. The congress will be divided into sections which will be devoted to eugenics, infant hygiene, medical and surgical pediatrics, pedagogy, and legislation. The congress will be presided over by Sr. Palavicini and among the members of the organizing committee are Sr. E. Chávez, former under-secretary of public instruction, and Drs. Rafael Carrillo, Roque Macouzet, and others. The secretaries of the committee on organization are Drs. Luis S. Viramontes and S. Uribe Rivera, whose address is: Apartado postal No. 909, Mexico City, Mexico.

The Study of Typhus Fever

The Comisión Central para el Estudio del Tabardillo has received a subsidy from the federal government amounting to 25,000 pesos (about \$12,500) for the present fiscal year, which will be expended subject to the discretion of the dean of the National University. This gift from the authorities has impressed physicians very favorably and it is hoped that it may yield some positive results, especially in view of the fact that Noguchi has offered to aid the commission with his advice in regard to parasitologic investigations.

Marriages

ABRAHAM I. WEINSTEIN, Richmond, Va., to Miss Virginia Elizabeth May of Charleston, S. C., February 1.

EARL C. WATERBURY, Newburgh, N. Y., to Miss Elmina Elizabeth Benoit of Ottawa, Ont., February 4.

HARVEY S. KOONS, New Castle, Ind., to Miss Izetta Harrigan of Bloomington, Ind., January 20.

EFFIE LOUISE ABBOTT to Mr. Gilbert Wilson Morton, both of Jacksonville, Ill., February 21.

ISAO HIRATA, New Haven, Conn., to Miss Misao Kawasaki of Cincinnati, February 18.

Deaths

Lewis E. Lemen * Denver; Washington University, St. Louis, 1871; aged 70; once president of the Colorado State Medical Society; clinical professor of surgery in Denver and Gross College of Medicine; surgeon to the Union Pacific and Denver, Texas and Gulf railroads; president of the Denver school board for twelve years; a member of the state board of health, a member of the staff of St. Joseph's and Mercy hospitals; consulting surgeon to St. Luke's Hospital; health commissioner of Denver in 1893 and 1894; president of the Board of Commissioners of the Colorado Insane Asylum; died February 17, from aneurysm of the aorta.

Edward Geary Tuttle, New York; New York Homeopathic Medical College, New York, 1889; aged 57; emeritus professor of gynecology in his alma mater; attending gynecologist to Flower Hospital; attending surgeon to the Yonkers Homeopathic Hospital and Maternity; consulting surgeon to St. Mary's Hospital, Passaic, N. J.; Middletown State Homeopathic, White Plains, and White Plains Hospital, New York, and Ann May Memorial Hospital, Asbury Park, N. J.; died, February 29.

John Dean Hall, Colonel, M. C., U. S. Army, retired, Washington, D. C.; College of Physicians and Surgeons in the City of New York, 1867; aged 77; who entered the Army as assistant surgeon, November 16, 1868; was promoted to captain in 1871, to major in 1889, to lieutenant colonel and deputy surgeon general in 1901, and to colonel and assistant surgeon general in 1903, and was retired by operation of law, March 18, 1906, on attaining the age of 64; died, February 25.

Harry Rodgers Lemen, Alton, Ill.; Washington University, St. Louis, 1893; aged 49; a member of the Illinois State Medical Society; Captain M. R. C., U. S. Army; a veteran of the Spanish-American War; later serving in the Philippine Islands, in the Boxer Rebellion in China, and in the Russo-Japanese War; while driving his automobile over a grade crossing in Alton, February 21, was struck by a train and instantly killed.

Albert Weil * Peoria, Ill.; Rush Medical College, 1893; aged 55; a member of the staff of the Deaconess and Proctor hospitals, also a druggist; county physician of Peoria County for sixteen years; once health commissioner of Peoria; local surgeon of the Chicago and Alton, Burlington, Peoria and Pekin Terminal and Illinois Traction systems; died, February 20, from heart disease.

Ver Nooy Wayland Weed * Brooklyn, N. Y.; College of Physicians and Surgeons in the City of New York, 1900; aged 42; associate surgeon to the Inshwick, Jamaica and Swedish hospitals, and a member of the staff of the Consumptives' Home; died in the Neurological Hospital, Manhattan, February 26, from cerebral hemorrhage.

John Oliver Sandercook, Oklahoma City, Okla.; St. Louis, 1871; aged 70; contract surgeon U. S. Army, with service in Indian campaigns under Generals Merritt and Crook; superintendent of the Board of Health of Canadian County, Okla., from 1902 to 1908; died in Denver, February 6, from pneumonia.

Alonzo Festus Burnham * Quincy, Ill.; Rush Medical College, 1878; aged 66; for many years connected with the state hospitals at Jacksonville and Bartonville, and more

recently physician at the Old Soldiers and Sailors' Home, Quincy; died February 20, from bronchopneumonia.

Augustus F. G. Zurhorst, Oakfield, N. Y.; Western Reserve University, Cleveland, 1869; aged 72; a member of the Medical Society of the State of New York; a veteran of the Civil War; once supervisor and postmaster of Oakfield from 1914 to 1919; died, February 21, from peritonitis.

Livingston Spraker Hinckley * Newark, N. J.; Bellevue Hospital Medical College, 1878; aged 64; for seventeen years medical superintendent of Essex County Hospital for the Insane, Newark; died in St. Barnabas Hospital, Newark, February 22, from pneumonia.

John Carroll McGinnis * Martin's Ferry, Ohio; Miami Medical College, Cincinnati, 1901; aged 41; who served during the World War as Captain, M. C., U. S. Army, and was discharged, March 20, 1919; died in the Cincinnati Sanatorium, February 21.

David Gildner, Rockwood, Pa.; University of Wooster, Cleveland, 1883; aged 71; disappeared mysteriously, Nov. 8, 1919, and is believed to have been murdered. His dismembered body was found encased in ice in a swamp near Searight, Pa., February 15.

Paul Henry Piper * Detroit; University of Michigan, Ann Arbor, 1918; aged 28; an intern in St. Mary's Hospital, Detroit; while delirious from pneumonia, leaped from a third story window at the hospital, February 14, and was instantly killed.

Charles William Hadley, Columbus, Ohio; Ohio State University, Columbus, 1912; aged 36; a member of the Ohio State Medical Association; instructor in obstetrics in his alma mater; died, February 20, from pneumonia following influenza.

Thurman Ross Beaver, Akron, Ohio; Indiana University, Bloomington and Indianapolis, 1910; aged 31; captain, M. R. C., U. S. Army, during the World War, and discharged, June 21, 1919; died, February 13, from pneumonia following influenza.

Alfred Hugh Fowler, Chicago; Rush Medical College, 1904; aged 42; a member of the Illinois State Medical Society; died in Wesley Memorial Hospital, Chicago, March 3, from chronic nephritis, complicated with cholecystitis and hepatitis.

Henly W. Allen, Boulder, Colo.; College of Physicians and Surgeons, Keokuk, Iowa, 1867; aged 82; a member of the Colorado State Medical Society; formerly president of the board of education of Boulder; also a druggist; died, February 14.

George W. Bean, Kansas City, Kan.; Eclectic Medical University, Kansas City, Mo., 1902; aged 78; a veteran of the Civil War; also a Presbyterian clergyman; died in the Soldiers' Home Hospital, Leavenworth, Kan., February 16.

Howard A. Wilson, Woodbury, N. J.; Jefferson Medical College, 1884; aged 60; a member of the Medical Society of the State of New Jersey; once coroner of Gloucester County; died in his office, February 21, from cerebral hemorrhage.

Frederick M. Brougher, Belen, Miss.; Memphis, Tenn., Hospital Medical College, 1900; aged 62; a member of the Mississippi State Medical Association; health officer of Quitman County; died, February 14, from heart disease.

Wiley A. Jones, Cantril, Iowa (license, Iowa, practitioner, 1887); aged 78; a practitioner for fifty-three years; once mayor of Cantril; surgeon of the Tenth Iowa Volunteer Infantry during the Civil War; died, February 17.

Thomas Rutledge Bass, Lafayette, Ind.; Indiana University, Bloomington and Indianapolis, 1909; aged 36; surgeon in chief of the Indiana State Soldiers' Home Hospital, Lafayette; died, February 15, from pneumonia.

Wallace Miles Knowlton, Newton, Mass.; University of Vermont, Burlington, 1880; a member of the Massachusetts Medical Society and of the American Medico-Psychological Association; died in Boston, February 6.

Joseph M. Finarty, Knoxville, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1877; aged 72; a member of the Iowa State Medical Society; a veteran of the Civil War; died, February 16, from angina pectoris.

Moses Zeller, Mt. Vernon, N. Y.; Fordham University, New York, 1919; aged 26; an intern in the Lincoln Hospital and Home, the Bronx; died in that institution, February 27, from encephalitis lethargica.

Elisha Price Merritt * Atlanta, Ga.; Atlanta (Ga.) School of Medicine, 1912; aged 34; secretary of the Fulton County

* Indicates "Fellow" of the American Medical Association.

Medical Society; a specialist in genito-urinary diseases; died, February 15, from pneumonia.

Charles William Weaver, Grand Rapids, Mich.; Fort Wayne (Ind.) College of Medicine, 1887; aged 55; died in the Detention Hospital, Grand Rapids, February 16, from poisoning by denatured alcohol.

Louis A. Turnbull, St. Louis; Missouri Medical College, St. Louis, 1888; aged 55; for many years a resident of Mexico; died in the Alexian Brothers' Hospital, St. Louis, February 17, from pneumonia.

George Washington Brown, Pratt City, Ala.; Atlanta (Ga.) Medical College, 1877; aged 72; a member of the Medical Association of the State of Alabama; died at an infirmary in Birmingham, February 15.

Harvey George Alexander, Deal Island, Md.; University of Maryland, Baltimore, 1891; aged 50; a member of the Medical and Chirurgical Faculty of Maryland; died, February 12, from influenza.

Harvey G. Hieber ☉ Los Angeles; Northwestern University Medical School, Chicago, 1903; aged 40; formerly of Thief River Falls, Minn.; died in Monrovia, Calif., January 17, from tuberculosis.

Howard Miles Jump ☉ Kelley's Island, Ohio; Toledo (Ohio) Medical College, 1895; aged 52; physician of Kelley's Island for two years; died, February 21, from pneumonia following influenza.

James Evans Kendrick, Luverne, Ala.; University of Alabama, Mobile, 1869; aged 74; a member of the Medical Association of the State of Alabama; a Confederate veteran; died, February 15.

John E. Douglass, Cincinnati; Medical College of Ohio, Cincinnati, 1883; aged 59; medical director of the Western and Southern Life Insurance Company for thirty-two years; died, February 14.

John Waldo Booth, Binghamton, N. Y.; Northwestern University Medical School, Chicago; 1870; aged 84; a member of the Medical Society of the State of New York; died, February 14.

Edward Dormanio Hall, Meriden, Conn.; Harvard University Medical School, 1873; aged 68; a member of the Connecticut State Medical Society; died, February 19, from pneumonia.

Michael F. Murray, Chicago; Rush Medical College, 1891; aged 59; a member of the Illinois State Medical Society; died, March 3, from gangrene of the foot following arteritis obliterans.

Frank M. Brundage, Conyngham, Pa.; Jefferson Medical College, 1874; aged 68; for eight years United States consul at Aix la Chapelle, Germany; died in Scranton, Pa., February 21.

Walter Meeker Cress, Clark's Summit, Pa.; University of the City of New York, 1893; aged 55; a member of the Medical Society of the State of Pennsylvania; died, February 17.

Nathaniel George McManus, Philadelphia; University of Pennsylvania, Philadelphia, 1901; aged 42; died in St. Joseph's Hospital, Philadelphia, February 18, from heart disease.

Peleg Francis Walker, Providence, R. I.; Boston University, 1881; aged 60; for thirty years a member of the school committee of Providence; died, February 27, from heart disease.

Guy Marshall McDowell, Bay City, Mich.; Ohio Medical University, Columbus, 1906; aged 39; a member of the Michigan State Medical Society; died in Detroit, February 16.

William Adolph Myers, Brooklyn; University of the City of New York, 1888; aged 53; one of the founders of the Bushwick Hospital; died, February 16, from heart disease.

David Hamilton Lewis, Washington, Pa.; Jefferson Medical College, 1877; aged 69; died in St. Francis' Hospital, Pittsburgh, February 17, the result of a nervous breakdown.

Matthew N. Alexander, Pleasant Shade, Tenn.; University of Tennessee, Nashville, 1896; aged 61; a member of the Tennessee State Medical Association; died, February 10.

Jokshan Freymann, Kansas City, Mo.; Cincinnati College of Medicine and Surgery, 1877; aged 73; a member of the Missouri State Medical Association; died, February 13.

Sharps M. Snyder, Greenwich, N. J.; University of Pennsylvania, Philadelphia, 1865; aged 78; died about January 24.

Charles Zuppann, Ballwin, Mo.; Rush Medical College, 1877; aged 57; a member of the Missouri State Medical Association; died, February 15, from heart disease.

John Blake McKay, Marion, Ind.; Trinity Medical College, Toronto, 1904; aged 47; died in the Grant County Hospital, Marion, February 14, from pneumonia.

Robert S. Knode, Omaha; Miami Medical College, Cincinnati, 1867; aged 77; formerly secretary of the American Rhinological Association; died, January 26.

William C. Hodges, Chesterville, Ohio; Columbus, Ohio, Medical College, 1881; Homeopathic Hospital College, Cleveland, 1892; aged 61; died, February 15.

Alfred Walton, Philadelphia; Harvard University Medical School, 1879; aged 62; died at his country home, Woodbury, N. J., February 22, from heart disease.

John Havemeyer Daniels ☉ Buffalo; Niagara University, Buffalo, 1895; aged 51; died in Buffalo General Hospital, February 13, from cerebral hemorrhage.

Thomas Walter Scott ☉ Rushville, Ill.; Missouri Medical College, St. Louis, 1884; aged 71; once mayor of Rushville; died, February 19, from heart disease.

Benjamin Franklin Makepeace ☉ Farmington, Me.; University of the City of New York, 1887; aged 60; died February 16, from lobar pneumonia.

Edward C. Pearse, Braddock, Pa.; New York Homeopathic Medical College, New York City, 1900; aged 45; died, February 14, from pneumonia.

Frederick Kenner Fisher ☉ Galveston, Texas; Tulane University, New Orleans, 1873; aged 67; died, February 11, from valvulus heart disease.

Frank Hamilton Whittemore ☉ New Haven, Conn.; Bellevue Hospital Medical College, 1874; aged 65; died, February 26, from pneumonia.

Milton Keim, Philadelphia; University of Pennsylvania, Philadelphia, 1872; aged 74; a graduate in dentistry in 1866; died, February 24.

John Wellington Moriarty, Churubusco, N. Y.; University of Vermont, Burlington, 1891; aged 62; died, February 9, from pneumonia.

Mary Johnson Cochran, Chester, Pa.; Homeopathic Hospital College, Cleveland, 1889; died, February 12, from pneumonia.

Jennie Holman Griffin, Troy, N. Y.; Cleveland Medical College, Homeopathic, 1895; aged 52; died, February 17, from pneumonia.

Frederick William Ritter ☉ Tannersville, Pa.; Jefferson Medical College, 1901; aged 52; died, February 23, from pneumonia.

George W. Bahn ☉ Spring Grove, Pa.; University of Maryland, Baltimore, 1881; aged 63; died, February 13, from pneumonia.

Belle Ogden Constant, Chicago; Hahnemann Medical College, Chicago, 1917; aged 49; died, February 19, from osteosarcoma.

Mark Rowe, Paris, Ill.; Eclectic Medical Institute, Cincinnati, 1866; aged 85; died, February 14, from bronchitis.

Giacomo Abraham Senigaglia ☉ Nyack, N. Y.; Cornell University, New York, 1909; aged 31; died, February 24.

Bernard Daly, Lakeview, Ore.; University of Louisville, Ky., 1887; aged 61; died in Livermore, Calif., January 26.

Frank Amos Rhoads, Pittsburgh; College of Physicians and Surgeons, Baltimore, 1882; aged 60; died, February 6.

Herbert Daniel Dieterle, Ann Arbor, Mich.; University of Michigan, Ann Arbor, 1918; aged 26; died, February 26.

Frank Edward Fletcher ☉ Ashland, Wis.; University of Michigan, Ann Arbor, 1865; aged 76; died, February 18.

Clarence R. Seeley, Attica, N. Y.; University of Buffalo, N. Y., 1873; aged 71; died in Miami, Fla., February 6.

J. Rodley Rundlett, Delavan, Wis.; Rush Medical College, 1868; aged 74; died, February 8, from septicemia.

Frank Warren Merritt, Jay, Me.; University of Vermont, Burlington, 1889; aged 62; died, January 25.

Fred Swartzlander, Omaha; Jefferson Medical College, 1872; aged 72; died, February 23.

Ira Hersia Leslie, Verona, Wis.; Rush Medical College, 1887; aged 58; died, January 8.

Edwin B. Reed, Ashbury Park, N. J.; Jefferson Medical College, 1884; died, March 1.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

HEPATOLA

A physician in Saskatoon, Saskatchewan, sends THE JOURNAL an advertisement from a local paper, reading:

OPERATIONS UNNECESSARY

HEPATOLA removes Gall Stones, corrects Appendicitis in 24 hours without pain. Registered under Pure Food and Drug Acts. \$6.00.

Profitable quackery dies hard. In the United States "Hepatola" was declared a fraud by the federal authorities in 1917 and the Hepatola Company was denied the use of the United States mails. Hepatola was claimed as the discovery of one "Dr. V. M. George" of Columbus, Ohio. So far as THE JOURNAL'S records show, and they are the most complete extant and based on official data, V. M. George is not, and never has been, licensed to practice medicine. In 1912 George was sending out letters to physicians stating that he had "retired from active practice several years ago" and that the "varied and valuable experience" that he had obtained while in practice had taught him "many things." Especially had it resulted in his discovering "a treatment

Dr. V. M. George
2308 N. High Street
COLUMBUS, OHIO

May 15, 1912

Dear Doctor:-

I retired from active practice several years ago, having been engaged, up to that time, mostly in Sanatorium work. That means a varied and valuable experience. It taught me many things, but most of all needed was a treatment that would remove gall stones through the bowels. This, I have succeeded in doing in 24 hours, without pain or danger, or the use of poisonous drugs. The same treatment, with slight modification, will apply to both appendicitis and typhlitis. I make no exception to the claims of this treat-

Reproduction (greatly reduced) of the letter head and opening statements made by V. M. George in 1912 when he attempted to interest physicians in his "cure" for gallstones.

that would remove gallstones . . . in twenty-four hours without pain or danger or the use of poisonous drugs." Further, "the same treatment with slight modification, will apply to both appendicitis and typhlitis." George's proposition was that physicians, instead of sending their gallstone patients to the hospital for operation, should let him treat them by his nonsurgical method. Apparently, George was not very sanguine of his venture for he said:

"The knife treatment has apparently so ossified any nascent ambition because of the hospital fees, that the average doctor is fearful to even think of any other modus operandi, lest it might destroy the very source of his existence."

In order, presumably, to fight the devil with his own weapons—and incidentally reap the reward of virtue—George suggested that

" . . . you permit me to work in harmony with you and give you the same percentage of fees as is given by the hospitals."

At the same time that V. M. George was attempting to interest the medical profession under his own name—an unsuccessful attempt as it proved—he was, under the name "Hepatola Company" appealing to the public to take Hepatola for the cure of gallstones and appendicitis. In fact, he also recommended it to persons who were perfectly well. The slogan of the Hepatola concern was "Avoid the knife." At the bottom of each page, set off from the reading matter and printed in italics one read:

"Avoid the knife—and save money"
"Avoid the knife—save your appendix"
"Avoid the knife—honeycombed with danger"
"Avoid the knife—everything for gain"

And then there were these warnings:

"When you once notice a suspicious pain in the right side, radiating to the back, that spells trouble. If you consult your physician, he will tell you right away, gall stones, appendicitis, or serious abdominal trouble. That means an operation. Don't entertain it for a minute, investigate Hepatola."

"Some fine day there is going to be an end to this promiscuous cutting by the doctors. The law protects them, and if you happen to die that closes the chapter—for the doctor. Not for the stricken family, however, who might have been relieved had they known of 'Hepatola.'"

The postoffice authorities finally got around to Mr. George and his Hepatola Company. Hepatola itself was turned over to the federal chemists for analysis and, as might have been expected, was found to be the same old fake gallstone trick—that of giving the victim a large dose of some bland oil and following it up with a saline. The soapy concretions that are voided following this dosing, are the "gallstones" which the "treatment" removes. Here is what the federal chemists reported:

"POWDER: This is an ordinary seidlitz powder, containing rochelle salts, sodium bi-carbonate and tartaric acid.

"LIQUID: This is an ordinary olive oil colored with a coal tar dye and slightly flavored with peppermint."

The same old humbug with ingredients essentially identical with "Fruitola" and "Mayr's Wonderful Stomach Remedy." Hepatola was a mail-order proposition and thus laid itself open to action on the part of the postoffice authorities. Fruitola and Mayr's Stomach Remedy, although, in the past, sold under claims just as ridiculous have always been handled through the "recognized channels" of the retail drug trade. They are still doing business; the Hepatola Company has been debarred from the use of the United States mails. The Canadian authorities might well investigate this Saskatoon industry. Possibly such an investigation would save, if not lives, at least money, for our northern neighbors.

Correspondence

SARCOMA OF THE UTERUS AND ITS RELATION TO ROENTGEN THERAPY*

To the Editor:—In a paper published in the *American Journal of Obstetrics and Diseases of Women and Children* (March, 1914) it was pointed out that the occurrence of sarcomas or of sarcomatous change in uterine fibromyomas was relatively frequent.

A careful study of 250 cases was made at that time, and twelve sarcomas were found that had been removed by operation. In only two instances was the diagnosis made, and then only at the time of operation. It was shown that symptomatically these malignant cases as a rule offered no distinctive diagnostic criteria, and for that reason it was difficult to differentiate clinically the malignant from the non-malignant cases. In other words, it was practically impossible to say definitely that a case supposedly a fibromyoma and therefore amenable to roentgen-ray therapy was not really harboring a malignant tumor. Two of the patients after operation developed extensive recurrences and died; all the others apparently did well.

In view of the frequency of these malignant cases, and because of the difficulty of preoperative diagnosis, it was urged that the roentgen-ray treatment of fibroid, especially about the period of the menopause, was hazardous.

In a subsequent study of 290 additional cases there were found ten sarcomas, making a total of 540 cases with a percentage of 4.07 sarcomas. These figures, which embody the results of a study of the material in a large metropolitan hospital, represent a frequency that cannot be set aside arbitrarily. In view of these figures, what must be our attitude toward the roentgen treatment of uterine fibroids that are unassociated with the usual diagnosticable compli-

* Work done under tenure of a George Blumenthal, Jr., fellowship.

cations, such as diseased adnexa, ovarian cysts, or other tumor conditions of the ovaries or tubes?

That the sarcomas occurring in fibroids are malignant there can be no doubt; cases in my own series and the many published reports show that they recur after operation, metastasize and lead ultimately to the death of the patient. On such a basis and because of their inaccessibility, one would be inclined to say that it is temporizing or worse to irradiate a patient who may have a malignant tumor.

The literature on the roentgen treatment of fibroids now teems with statistics, and the results are the quoted observations over long periods of time. To my knowledge there are no cases in the literature of fibroids in which, after or during the roentgen treatment of fibroids, a malignant condition has developed locally. Nor are there any reported cases that during the roentgen-ray treatment or subsequently showed metastatic deposits from a primary uterine tumor. These reports must be accepted as showing that a series of cases, now mounting into thousands, undoubtedly with undiagnosed sarcomas among them, have been irradiated and cured or at least rendered innocuous, for the period of observation. It cannot be argued that the bad results have not been reported, and we must therefore alter our point of view as regards the roentgen-ray treatment of fibroids. It must be stated that, in view of the frequency of sarcomas in the cases in which operation is performed, the same percentage must occur in the cases in which irradiation has been employed. If after irradiation and prolonged periods of observation no malignancy develops in the uterus and no metastases occur, then we are bound to say not only that the roentgen ray causes a beneficent result in the treatment of fibroids but also that in those cases complicated by sarcomatous change or those cases of sarcoma not diagnosed, the same arrest in growth and retrogression of size and disappearance of symptoms takes place as in the ordinary fibroid. Whether or not subsequent observation will show that these conclusions are erroneous one cannot say; but at least if the reports of the roentgenotherapist are comprehensive, then roentgen-ray therapy has a decided place in the treatment of fibroids irrespective of whether or not the diagnosis of sarcoma or of sarcomatous degeneration was overlooked.

In a previous paper it was stated that the sarcomatous elements may not be giving rise to any special symptoms, and that thus temporarily one is lulled into a feeling of false security. It was contended that until it was proved by a long period of observation that the roentgen ray might have a curative effect on uterine sarcomas, it was unfair to expose a patient to the unnecessary risk and delay that the roentgen treatment in those cases would entail. It seems that such a period of observation has now passed and that we must realize that the roentgen ray, when applied in the approved method to uterine fibroids whether or not complicated by sarcoma, is productive of favorable results in properly selected cases.

Pathology, Mount Sinai Hospital.

REVISION OF THE PHARMACOPEIA

To the Editor:—Your recent announcement concerning the coming meeting of the U. S. Pharmacopoeial Convention (THE JOURNAL, Feb. 28, 1920, p. 613) is most timely. It is important that every medical society and college privileged to send delegates to the convention should do so. The Pharmacopoeia should furnish standards of purity and strength of drugs needed by the profession. It also should tell how to make standard preparations of them.

Drugs that are useful are those which possess physiologic or pathologic action. Unfortunately, the Pharmacopoeia still contains some that possess neither. It is still more encumbered by a multiplicity of preparations that must now be learned by pharmacists and physicians. Two preparations, or in some instances three or four of each drug, are all that are needed. The Pharmacopoeia should point out these best preparations and necessary drugs; others should be omitted.

The latest revision of the Pharmacopoeia was about five years in making. If cut to proper proportions, the revision could be made much more promptly, for it takes as long to prepare the description of unnecessary and superfluous drugs and preparations as of necessary ones. It is so important for medical men to possess standards for the drugs and preparations which they use that they must take interest in the revising of the Pharmacopoeia. This should not be left altogether to retail or manufacturing druggists and, above all, the manufacturers of trade-marked and proprietary preparations.

I hope that you will continue to agitate this subject until the medical profession takes the active part in the affairs of the Pharmacopoeia which it should.

N. S. DAVIS, M.D., Pasadena, Calif.

"WHAT IS SO-CALLED SCIENTIFIC DRINK CONTROL?"

To the Editor:—Your editorial "What Is So-Called Scientific Drink Control?" in THE JOURNAL, February 14, is presented at a time when this question is uppermost in the minds of many thoughtful students, and when the question as to what is an intoxicating beverage is being submitted for a correct answer to the medical profession. The national prohibition act has raised the question, What is an intoxicating beverage? It would appear that the term "intoxicating" is used in the ordinary, reasonable and accepted sense, and is synonymous with drunkenness. Doubtless this question will finally be officially determined as a result of scientific tests made by competent medical authorities. Only the other day the New York State Bureau of Health was requested by the legislature of that state to study this phase of the alcohol question and to report its findings, in order to guide the legislature in arriving at a conclusion as to what is an intoxicating beverage. As you rightly say, it is remarkable that, while much has been written with reference to alcohol, there is yet much to learn with reference to its action. This would appear to apply especially to alcohol in dilute solutions and to alcohol when it appears in combination with other substances, as in the malt beverages. Practically all the available data of experimental work done prior to 1919 refer to relatively strong solutions of alcohol.

That the effects of different doses of alcohol may yield different results at times is referred to by Dodge and Benedict, from whose work I quote:

In addition to the main experimental precautions we systematically varied the alcohol dose. This was done for the following reasons. In the first place, it is a fact that different doses of some drugs produce quite different physiological effects amounting even to a change of sign. That this is true of alcohol seemed to be indicated in more than one experimental investigation.

When one considers the complex chemistry of beer, there is reason for believing that its alcohol is modified and that for this reason beer with a low alcohol content is rendered nonintoxicating. Recent experiments have been conducted in this country to determine whether or not a beverage with an alcohol content of 2.75 per cent. by weight of alcohol is intoxicating. As a result, the conclusion was reached that malt beverages with an alcohol content of 2.75 per cent. by weight are not intoxicating as that term is ordinarily used, and the reasons assigned for this are in the main in accord with the work of Mellanby which you refer to. These were published in the "Hearings before the Subcommittee of the Committee of the Judiciary of the United States Senate, 66th Congress, First Session on the Bills to Prohibit the Liquor Traffic, and to Provide for the Enforcement of such Prohibition and the War Prohibition Act." Part 3. Government Printing Office Washington, D. C.

While it is, of course, true that these experiments have dealt with a limited number of subjects, and it is also true, as you state, that nowadays scientific experiments are being conducted on a national scale, it is also a fact that for some years past there has been conducted a scientific experiment on a national scale with reference to the effects of malt beverages of low alcoholic content. I refer to the people of

Norway, who are held up to us as models of righteousness, thrift and sobriety, and among whom there is sold, with practically no restrictions whatsoever, beer with an alcoholic content of 2.75 per cent. by weight.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

NERVE AND SPINAL CORD COMPLICATIONS OF MALARIA

To the Editor:—What are the principal nerve or cord lesions following malarial fever. I believe I read a paper in THE JOURNAL some time ago, but I cannot recall it at present.

SAMUEL GINSBURG, M.D., Buffalo.

ANSWER.—Among the rarer complications of malarial fever which have been observed are: paraplegia, which may be due to a peripheral neuritis or to changes in the spinal cord; hemiplegia, which may occur in the pernicious comatose form or, occasionally, at the very height of a paroxysm; spinal irritation; paresis; meningitis; psychoses; aphasia; acute ataxia, and, in a few cases, symptoms of disseminated sclerosis.

REQUEST FOR MATERIAL TO AID MALARIA INVESTIGATION

To the Editor:—The undersigned would like to enter into communication with physicians who may be located in malarial districts, in reference to securing postmortem material from fatal cases of malaria, for purposes of investigation. Any aid that may be afforded us in this connection we should deeply appreciate.

Pennsylvania July Examination

Dr. Thomas E. Finnegan, secretary of the Pennsylvania Bureau of Medical Education and Licensure, reports the written and practical examination held at Philadelphia and Pittsburgh, July 8-10, 1919. The examination covered 5 subjects and included 50 questions. An average of 75 per cent. was required to pass. Of the 192 candidates examined, 172 passed and 20 failed. Seven candidates were licensed on Army and Navy credentials. The following colleges were represented:

College	PASSED	Year Grad.	Number Licensed
George Washington University	(1914)		1
Howard University	(1917), (1918, 3)		4
University of Louisville	(1917)		1

Miscellany

THE "CRIME OF VACCINATION"

Old St. Joe Does Not Take the Antis Seriously

A few weeks ago the lady propagandist who goes over the country giving a series of talks against vaccination, was in St. Joseph, Mo. At one of the meetings various speakers attacked vaccination as a "crime" and dilated on its fearful effects on the minds of its victims. While pausing for breath one of the speakers, mistaking a physician in the audience for the city health officer, accused him of being afraid to say anything. The physician in question was Dr. W. L. Kenney of St. Joseph, who immediately arose to the occasion. Here, according to the *St. Joseph Gazette*, is what happened:

"How many of us adults have submitted to this crime of vaccination?" he asked.

"Here, here," cries arose, and about fifty raised their hands. None were louder than the speaker who had just finished.

"How many of these have been 'crippled in the mind' by this vaccination?" Dr. Kenney then asked, smiling. In the hush that followed, the doctor said, "Thank you," and left the room.

The indignation that followed is well described by the newspaper, but can as easily be imagined. As a result, Dr. Kenney was challenged by the lady propagandist previously mentioned to debate the question of vaccination. Dr. Kenney's only reply was a statement which he gave to the *Gazette*. It is worth reproducing:

David went to his challenger with much greater confidence than I can. Who am I to match this Goliath of the anti-orthodox? I am only an oculist. But chiefly I am afraid to debate with the lady. I have lost a daily debate with one certain lady for twenty years and I know the odds are too heavy.

Besides, the crippling effect of vaccination on the mind is recalled to me every time I see that scar on my arm. It isn't fair of an unvaccinated, uncrippled antivaccinationist to pull me into a hopeless argument.

WHO HAS FOOLED THEM?

Now, if it were a question of facts and proofs instead of debate, there could be a decision rendered. But a decision has been rendered on proofs before the public for several generations, so that the man in the street, as a matter of common knowledge, knows that vaccination will check an epidemic by preventing smallpox. Millions of people for half a dozen generations and in various climes and countries have voted for compulsory vaccination. Who has fooled these millions? Why haven't the antis saved past generations? They were more active then than now, yet generation after generation votes to vaccinate the other fellow. Doctors are chumps to cut off a source of profit by preaching to the people. They prevent typhoid by vaccination, and typhoid used to be always with us. Poor business men, these doctors! However, the antis claim that mammoth trusts control the doctors, so that they are willing to lose a \$200 case of typhoid for a \$5 vaccine fee.

FEEL A PROFESSIONAL RESPONSIBILITY

Why can't the antis believe that doctors feel a professional responsibility toward humanity, and when knowledge comes to them they give it to the world? That is what the antis claim to do, so why can't they understand that others may feel the zeal of the proselyter. But the antis protest that only the compulsory feature is objectionable to them and that they favor sanitation and lots of good things.

Yes, and they favor compulsory quarantine, for they know full well no other is effective. And they favor compulsory sanitation, for who will pay for expensive sanitation except the law requires it? Even then the doctors continually campaigning for enforcement of sanitation laws—the sneaking poisoners! Why, the evil-minded trust of medical men has eradicated yellow fever, a deadly disease indeed, and malaria, too, by urging compulsory laws they have suggested. Of course, it was for dollars or else some other trust bade them do it!

OTHER COMPULSORY LAWS

Don't antis know that we must have compulsory laws to raise taxes and we have compulsory traffic laws, compulsory educational laws, compulsory Sunday laws, compulsory mili-

tary laws, compulsory prohibition laws, and compulsory monogamy laws? And each one is necessarily compulsory, too. Besides the compulsion, the antis have urged that the vaccination may transfer bovine qualities. I grant that many do bellow like a calf at the time. The antis made this claim contemporaneously with the experiments on monkeys and arm-to-arm inoculation, and corpse-monkey-calf sequence of inoculation as quoted in recent handbills of the antis.

Recent speakers also claim the transference of the following, as taken from my notes: leprosy, tuberculosis, foot-and-mouth disease, influenza, typhoid, syphilis, cancer, heart and kidney diseases. And solemnly read the assertion of an outlaw doctor that the sore on the arm is nothing else than the chancre or initial sore of syphilis. We can so easily show the germs of syphilis and the blood tests are so dependable that any anxious anti can find out positively. However, I have yet to meet a case of real honest-to-goodness syphilis that couldn't tell me confidentially the precise source.

AS TO CANCER

Now, cancer next. Oh, cancer! what chills can be thrown by thy name! But the microscope shows positively and easily what tissue is cancer and what is not. It is very hard to inoculate and remains as a local tumor at the point of inoculation. It is possible to inoculate mice with their own kind of cancer, but almost impossible to inoculate cancer into the human family.

The antis solemnly say doctors can't say what causes cancer, therefore they can't say that vaccination doesn't. Well, they can't say what causes twins, but they do say that vaccination doesn't. The antis take statistics and show that cancer and pneumonia and insanity have been on the increase since vaccination came in. Well, so have divorces! Also the high cost of living! It seems more probable that in the past cancer was not diagnosed or reported. In fact, it is hard to get diseases reported in this present century.

In all debates the burden of proof is on the one who assaults an established thing or custom. I challenge the antis to bring the one-armed veterans of the antivaccination war who reside in St. Joseph into a gigantic parade on Saturday, each squad of four carrying in their right and lonesome hands a stretcher supporting a cripple less fortunate. Let them be captained by those who nearly lost an arm and let the battalions be marshaled by those who had smallpox despite vaccination. Let the nurses be ladies with pock-marked faces and a banner proclaiming the advantages of scars on the faces rather than on the arm. And for a general, try to find an anti who has been vaccinated and escaped without a crippled mind. Let this army parade into the east door of the courthouse and from the north or west door I will advance with an equal number of cases of smallpox, man for man. Then let all hold up their hands who object to vaccination!

THE CAMPAIGN AGAINST VENEREAL DISEASE IN SWITZERLAND

An association to combat the spread of venereal disease was formed in French-speaking Switzerland in 1918, and in October, 1919, it launched a vigorous general campaign over the whole of this part of the country by means of numerous local committees for small sections. The local group comprises physicians, teachers, clergy, and delegates from athletic and other clubs, etc., besides the municipal authorities. Each local committee works under general direction from the headquarters at Lausanne, and material for propaganda is provided. The aim is to decentralize the work as much as possible, starting innumerable foci for propaganda throughout the country.

Lantern slides are loaned and the lectures are widely advertised on the billboards: "Social Danger of the Venereal Diseases. Free public lecture by Dr. X and Senator X." A state or municipal authority always speaks in addition to the medical speaker. Pamphlets and circulars are distributed in assemblies of men and in factories. Series of conferences are given also for the sexes separately. Public lectures have thus already been delivered, according to a writer in the *Paris Médical*, to a total of twelve at Geneva, twenty at Neuchâtel and Lausanne, and from one to five at other points.

The fact that no protests are heard against the billboard announcements shows, the writer says, that the time is ripe for this open campaign. The halls are constantly crowded.

The expense is borne by subsidies from factories, etc., donations from individuals, and state appropriations. German-speaking Switzerland has an association of its own for the purpose, but it works on the centralization system, instead of the scattered foci plan of the Lausanne headquarters.

Medicolegal

A Valid Food and Soft Drink Health Ordinance

(*City of Portland v. Traynor (Ore.)*, 183 Pac. R. 933)

The Supreme Court of Oregon, in affirming, in two cases considered together, judgments of conviction of violating Ordinance 35013 of the city, providing for the licensing of persons conducting or working in food and soft drink establishments, holds that, under its charter, the city had a legal right to adopt the ordinance. The charter also makes it the duty of the bureau of health to enforce such an ordinance, and vests it with power to make the necessary rules and regulations for its enforcement. The ordinance provides that it shall be unlawful for any person to open for business, conduct or maintain, or cause to be opened, conducted or maintained, any food establishment in the city of Portland without first securing a license therefor. If, on investigation, the proposed location is found to be suitable for a food or soft drink establishment, and in proper sanitary condition, according to the ordinances of the city and the rules and regulations of the United States with reference to plumbing, water supply, ventilation and cleanliness, the bureau of health shall issue to the applicant a permit for such establishment. The ordinance also provides that it shall be unlawful for any individual to be employed or to work in any food establishment without having first obtained a health certificate, or for any employer to hire any individual without such certificate, and it is specified that the certificate is to be renewed quarterly, and that no certificate more than three months old shall be recognized by any employer. Any person desiring to secure a certificate of health shall present himself to the bureau of health at least once every three months, and, if the person is found by the bureau to be physically fit and free from diseases that are dangerous to the public, the bureau of health shall issue to such person a certificate of health entitling such person to work in a food establishment or soft drink establishment. The term "food establishment," whenever used in the ordinance, shall mean and include every place in the city where food products are sold or offered for sale or served to the public, or manufactured, produced, concocted, prepared or cooked for the public. The term "soft drink establishment" shall be deemed to mean every place in the city where drinks are sold, manufactured or served or offered for sale to the public. The word "person" shall mean any person, firm, or corporation. To carry out the provisions of the ordinance the city was divided into seven districts, and inspectors were appointed for each. It was their duty to examine all the food and soft drink establishments in the city, to ascertain whether the owners thereof were complying with the municipal health ordinances in the construction of their buildings and sale of their merchandise, and in particular to note whether employees coming in contact with soft drinks, groceries, fruit and vegetables with their hands were healthy and free from contagious or infectious diseases. A card index system was established, and after inspection the employees were required to report to the bureau of health, and to submit to physical examination, for which, under the terms of the ordinance, a nominal charge was made. If it was found by the inspectors that the premises where the business was to be conducted were sanitary and complied with the ordinances of the city, a license was then granted to conduct the business on the payment of an annual fee. If on examination an employee was found to be free from contagious or infectious diseases, a certificate was then issued to him by the bureau of health, authorizing him to handle and sell such merchandise in bulk,

as distinguished from canned or carton goods. The defendant was engaged in conducting a grocery store in the city, and refused to obtain a license for his business. He raised constitutional questions to the validity of the ordinance, but the court holds that it was valid. The defendant's contention that the medical examiners were careless and negligent in the discharge of their duties was not supported by the evidence; but, assuming that to be true, it would go only to the administration, and not to the validity, of the ordinance, and would not be a defense to the charge against him. Nor was it for this court to say whether or not the measure should have been enacted; that was a legislative, and not a judicial, question.

Stenographer Not Able to Bind Company for Operation

(*Producers' Oil Co. v. Green (Texas)*, 212 S. W. R. 68)

The Court of Civil Appeals of Texas, in reversing a judgment for \$150 that was obtained by the plaintiff, Dr. Green, against the oil company, says that the action was brought against the corporation and one Sherman to recover the reasonable value of services rendered in the performance of a surgical operation, known as suture of the patella, on one Earp, one of the company's employees who had been injured while in its service. The plaintiff sought judgment against Sherman individually only in the event that the corporation was not held. The undisputed testimony showed that Sherman was merely a stenographer and clerk in the office of one Clayton, the latter being a general officer of the company and head of the department in which Sherman worked, the actual operation of the corporation's business being divided into departments, each having a head. The jury found, on special issues submitted to it, that Sherman, before the service was rendered, requested Dr. Green to perform the operation on Earp under statement that the company would pay him for it, and that Sherman was authorized by the company to make such request and statement. But the evidence showed that at the time he made the request and statement the company was a subscriber to the workmen's compensation act, and had provided for the insurance of all its employees thereunder, which facts were then communicated to Dr. Green; and that, aside from such authority as legally might and actually did come to him from his superior officer, Mr. Clayton, Sherman had none whatever to bind the company to pay for medical services rendered to Earp, and Mr. Clayton had turned over to him only the matter of attending to the accident report in Earp's case, and not the management of it generally. Under all the circumstances, the court concludes that the jury's finding that Sherman was authorized by the oil company to make the arrangement stated with Dr. Green had no support; that the company was not liable, and that its request for a peremptory instruction embodying that view of the law should have been given. Private corporations with the limited charter powers of operating, drilling for and producing oil, as this one was shown to be, may not become bound on the mere ipse dixit or statement of such an underling for medical services, rendered, or to be rendered, under the circumstances here presented, to another of its employees. Corporations can be bound by their agents only when acting within the scope of their authority, and those dealing with such agents are not only chargeable with notice of, but, in case of controversy, have the burden of showing, the authority assumed to have been in fact possessed. Manifestly no such burden was met in this case. Even if it had been shown that Clayton knew all that Dr. Green said occurred between himself and Sherman, and had delegated to the latter every power he himself possessed for the corporation, a majority of the court is of the opinion that it would still not have been bound; this for the reason that the company had previously provided a method of caring for such contingencies by means of the insurance it had taken out for the benefit of its employees under the compensation act; and not even one of its general officers could substitute a different provision, or impose a liability on account of services rendered an employee, particularly in the absence of special authority from the board of directors.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Joint Annual Conference of the Council on Medical Education of the American Medical Association with the Association of American Medical Colleges and the Federation of State Medical Boards of the United States, held in Chicago, March 1-3, 1920

The conference met in the Congress Hotel and was called to order at 10 a. m. by Dr. Arthur Dean Bevan, Chicago, chairman of the Council on Medical Education.

Further Development of Medical Education

DR. ARTHUR DEAN BEVAN, Chicago: In calling your attention to certain tendencies and weaknesses, which I have felt should be pointed out and corrected, I do so with the feeling of optimism for what our medical schools are accomplishing and what we shall certainly accomplish within the near future. I feel strongly, however, that in developing the medical school as we are now very properly doing, as the medical department of the university, we must do so on very broad and practical lines and keep in mind the interests of the patient, of the profession, and the community and remember that medicine is not only a science but also an art.

At present in this country we are in a condition in which the professor in anatomy, physiology and the other laboratory branches and the laboratory worker in clinical medicine have been given too large a part in the task of reorganizing the university medical schools and in developing the medical curriculum. This tendency should be corrected. We should keep constantly in mind the fact that the first and highest duty of the medical school is to train competent practitioners of medicine, and this cannot be done by the college professor of embryology and comparative anatomy, or by the chemist working in a clinical laboratory or by the research worker in some isolated medical institute. These men are not competent to develop and control medical education along sound lines. Yet, that is unfortunately the tendency of the time. This problem should be met by placing the control of medical education where it belongs, in the hands of medical men.

First, we should insist that the teachers of the laboratory branches shall have a medical training, a medical point of view; that they keep in touch with the medical profession and the art and science of medicine, and that they realize that their first duty is to assist in training practitioners of medicine.

Secondly, we should insist that the teachers of the clinical branches shall have a broad training in both the science and the art of medicine; that they be great clinicians in their special fields, and that they be trained to understand not only what the medical student needs to know in their particular specialty, but also what anatomy and physiology, pathology and pharmacology the student needs to acquire to become

an expert practitioner in any particular field. Such teachers would bring about a better correlation of the clinical and laboratory branches. Fortunately, in the last twenty years, we have trained many such men in this country. There is an abundance of high class, well trained men to fill the places of the clinical teachers required.

The back bone of a medical faculty should consist of the professors of medicine, surgery, obstetrics and pathology. Such a group should control a teaching hospital and outpatient department, with adequate clinical and pathologic material and well equipped laboratories. The plant should be located where it can secure ample clinical material with little or no cost to the medical school. The affiliation of a large municipal, state or sectarian hospital with a medical school would be of mutual benefit, not only to the hospital and medical school but also to the community in which they are located.

The laboratory branches in medicine are important, but a medical school is a school to train physicians and not anatomists or physiologists. If the training of physicians is well done it will frequently result in training teachers and research workers at the same time as important and desirable by-products.

THE FINANCIAL SIDE OF MEDICAL EDUCATION

Many plans are now being developed apparently without any consideration of the cost of medical education. Fees of students average about \$150 a year, and the cost of a medical education is about \$450, and in many institutions \$1,000 or more, and is still mounting. The cost of running a hospital for medical teaching should never be charged to the medical school. It is not in the interest of the community for a medical school to create and maintain a hospital primarily for the teaching of medicine. The first purpose of a hospital is to take proper medical care of patients, and this function is best performed if it also fulfils the functions of medical teaching and medical research. The great municipal, state and sectarian hospitals should be placed at the disposal of our medical schools for teaching and research.

A state hospital in Iowa, operated primarily for the purpose of furnishing the best medical care to the people of the state, is very properly placed under the control of the State University of Iowa, and becomes the teaching hospital of the medical school. The Iowa plan has been well thought out and is so sound that many of our older medical schools might adopt it with profit to themselves.

The much discussed plan of all-time clinical teachers is a very costly one. It is so extravagant that it cannot be generally adopted by the medical schools of the country. Unless it has unlimited resources, a medical school should not consider the plan at all. Even a school with large resources can secure better results by adopting the more practical part-time plan for its clinical teaching. The all-time clinical teacher scheme has proved to be exceedingly costly; it is also exceedingly difficult to secure the most desired men with the restrictions that at once exclude the holder from the rewards of professional work well done. The all-time plan is an experiment that should be tried out in a few schools that can obtain the large endowments necessary.

The majority of medical schools should adopt the part-time plan. The teachers in the clinical departments should receive the same salaries as the professors in the other departments in the university, and should be required to devote the necessary amount of time to their positions. The college should insist, however, that their clinicians maintain positions as great clinicians and keep in contact with both the medical profession and the community. The clinician should be provided with a limited number of private beds in the hospital, and to these his private work should be limited. If the professor abuses his privileges, the university authorities should correct or eliminate him.

GRADUATE MEDICAL EDUCATION

There is a growing demand for graduate instruction in medicine which must be met by the universities of the country. Fifteen or twenty universities are so situated that they could establish satisfactory graduate medical schools.

The plan proposed includes the following propositions:

1. A complete and separate department for graduate work should be established. Certain men might work in both undergraduate and graduate departments, and certain laboratories and hospitals might be used in common; but in order to develop a graduate department of the best type, a complete separate faculty and plant is required.

2. This graduate school of medicine should furnish instruction of various kinds, as follows:

(a) For recent graduates who have completed their hospital internship and who desire to specialize in some clinical or laboratory field, a course of three years should be provided in a well organized clinic, where each assistant would be an essential part of the machinery, where he does clinical work, teaching and research work, and is given a real opportunity and responsibility in the handling of patients. At the end of such a three years of training, the assistant would be competent, in the absence of his superior, to conduct the clinic. At the end of such a course the student should be given a degree, Master of Science in Surgery, Ophthalmology, etc., or, if the assistant has taken a three-year course in a laboratory branch, a degree of Doctor of Philosophy, in Anatomy, Pathology, etc.

(b) For physicians who have been practicing for three or more years, a concentrated course of one to one and a half years should be provided in the clinical branches, leading to the same degree as granted to the men in the preceding group.

(c) A well planned course of from three to six months should be provided, in which practitioners could take special and thorough work in some limited field. For this they should receive no degree, but they might possibly be given letters stating that they have taken such a special course.

(d) There should be courses in which practitioners can brush up on several subjects, selecting their own subjects, the amount of time they devote being optional but ranging from a month to six weeks. This will numerically be probably the largest group. These practitioner courses are on the whole of great value to the medical profession and to the community. Of course, no degree or statement of attendance of any kind should be given for this work.

3. Courses should be provided for general practitioners who live near enough to the medical school to come once or twice a week to some clinical or laboratory course on some special subject.

Improvements in Medical Education in Sixteen Years

DR. N. P. COLWELL, Chicago: About forty of the 162 medical schools existing in 1906 were without laboratories and without clinical material. Nevertheless, in 1907 these institutions turned out from twelve to 105 graduates. Now most of the medical schools have five or more well equipped laboratories, and there is not one which does not have at least three laboratories. As to clinical material, most medical colleges now actually own or control a teaching hospital,

and there is not one which does not have relationship with a hospital in which at least amphitheater clinics can be held.

Methods of clinical teaching have been greatly improved. Formerly the amphitheater clinic largely prevailed in which the professor gave a lecture-clinic, or performed an operation before a large body of students. This has given way to the smaller group clinics at the patient's bedside. Patients are now regularly assigned to senior students, who write the histories, make the physical and laboratory examinations and suggest the diagnosis and treatment.

Since 1904 the proportion of medical schools requiring any college work for admission increased from only four, or less than 3 per cent., of the 160 medical colleges, to seventy-nine, or 92 per cent., of the eighty-five colleges now existing. All but one of the medical schools require that the premedical work be taken in a college of arts and science. (See Chart 1.)

The advantages in requiring that the premedical work be taken in approved colleges of arts and sciences are:

1. The physics, chemistry and biology are taught without reference to their special bearing on medicine. It is not known today what particular facts obtained in the study of these sciences will be most useful in the medical research of tomorrow.

2. The quality of the premedical work is assured since it is carried in the courses leading to the degree of Bachelor of Science in reputable colleges of arts and sciences. This provides also a satisfactory standard for measuring the value of irregular or so-called "equivalent" courses.

3. The student is free to make a final choice of his life work until he is best qualified to do so. He enters the classes leading to the Science degree; he has a chance to compare notes with those studying for other callings, and may find that some other line of endeavor appeals to him more than medicine. If

so, he can make the change without any loss of time, since his premedical courses are equally acceptable for admission to other departments. This freedom of choice is of great importance to the students, since from 10 to 30 per cent. change to some other calling before their two-year course is completed.

4. Students now enter medical schools with the benefit of two years in the college atmosphere, the contact with students in other departments, the social life, and the athletics, which are bound to influence their entire lives.

5. The arrangement is a safeguard against medical cults. It is seldom that a student who has studied genuine science in his courses in physics, chemistry and biology will be misled by the fallacious claims advanced by unscientific cults.

The one disadvantage of the arrangement is the lack of uniformity in the courses in physics, chemistry and biology given in different colleges or universities. This disadvantage will be corrected through the plan to secure more uniformity.

NO DEARTH OF MEDICAL STUDENTS

Early in the campaign for higher requirements of preliminary education, some feared that medical schools would

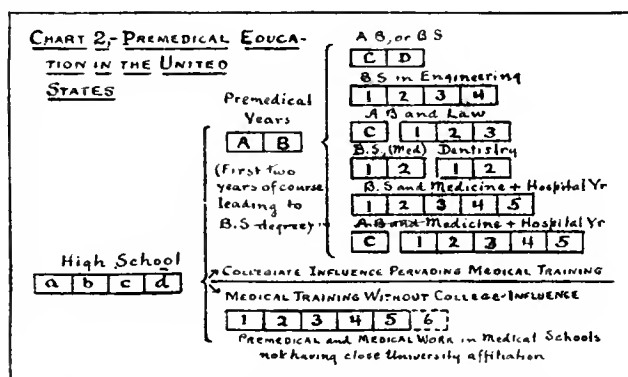

CHART 1.—MEDICAL SCHOOLS AND ENTRANCE REQUIREMENTS

The heavy line at the top shows the total numbers of medical schools existing in the various years. The horizontal shading (indefinite) shows those requiring for admission a four-year high school education; the vertical shading those requiring one year of college work and the heavy shading those requiring two years of college work.

Figures show (a) those requiring for admission a high school education or less; (b) those requiring one year of college work; (c) those requiring two or more years of college work.

be unable to secure students. A reduced enrolment in the first session naturally followed the adoption of the higher requirement; but in subsequent sessions, in all the better medical schools, enrolments have returned to normal proportions.

This chart shows (a) that the student is under the influence of college life and atmosphere during his two premedical college years; (b) that he is not required to make a final decision in regard to his life work until he has finished all premedical work, and (c) that at any time he can change to some other calling without difficulty.

LIMITATION OF ENROLMENTS

The limitation of enrolments by medical schools and reports of excessive numbers of premedical students have caused some alarm lest medical schools may not be able in future to admit all the well qualified students who apply. An investigation shows that the sixteen Class A medical schools which have limited their enrolments can care for 4,559 students. Thirty-nine medical schools report that their highest capacity with efficiency of teaching would enable them to care for 9,061 students. An estimate based on the inspection of thirteen other medical schools shows they can enroll and properly train about 1,810 students. The sixty-eight medical schools in Class A, therefore, can enroll without overcrowding 15,430 medical students or approximately 2,000 more than are at present enrolled in the eighty-five medical schools of the United States. By the addition of more teachers; or by the enlargement of laboratories, or by the completion of college buildings being planned or already in course of construction, the numbers of medical students who

CHART 3.—CAPACITY OF MEDICAL SCHOOLS UNDER LIMITED ENROLMENTS

can be satisfactorily taught could be further increased to 17,000 or 18,000 students. The existing medical schools, therefore, are more than adequate to meet present needs and in future as the numbers of students may increase, ample provision can be made for them.

There is a real demand for medical graduates to serve as interns in hospitals, but this demand could not be met even if the number of medical colleges and the number of grad-

uates annually should be doubled or trebled. The intern problem requires some other remedy:

(a) The internship might be extended to eighteen months or two years, by which the annual output of graduates would supply about twice as many hospitals.

(b) The hospitals might employ recent graduates to remain for several years as resident physicians or surgeons.

(c) Hospital assistants or nurses might be trained to do much of the work now devolving on the intern.

(d) The situation is relieved in some hospitals by the employment of stenographers who, at the time the patients are examined, take down histories from dictation by the members of the attending staff.

The Needs and Future of Medical Education; Ideals and Their Function in Medical Education

GEORGE E. VINCENT, President of the Rockefeller Foundation, New York: In order to measure achievement and to guide progress, there is need of ideals or standards. Without tests there is danger that opportunism, provincialism, even a narrow nationalism, will prevent the development of medical education on a broad, international basis.

In human institutions there are no absolute standards. The highest ideal may be approximated in a few medical schools in which methods may be tested and leaders trained, but it would be a serious mistake not to recognize various degrees of achievement. The influence of local conditions, the possibilities of economic support, and relations with other university units must be taken into account. All that can be confidently affirmed is that some institutions fall below any standard that can be recognized as guaranteeing results which will safeguard the public and protect the profession. The number of such schools in the United States grows steadily smaller.

There is danger that the existence of a standard may force a formal rather than a real compliance with ideals. A premature effort to conform to an accepted standard may do positive harm. For example, there is reason to believe that in the case of medical schools in the South, where high school systems have had to be developed within a brief period, there has been an overstimulation of secondary and college education; that three-year high schools have changed to a four-year curriculum with little or no additional resources or increases in numbers and efficiency of teaching staff, and that colleges have offered courses which they are not prepared to give efficiently. Moreover, the Class A of the American Medical Association, having been accepted by state boards of medical examiners and thus become a part of the official machinery has been extended in such a way as to produce serious anomalies. These will doubtless be largely removed as a result of the new survey which has recently been completed.

One of the ideals of modern medical teaching which needs constant emphasis is the provision of the best type of medical care for the sick. Laboratory and clinical methods must be thought of as a protection to the patient. Careful diagnosis, resourceful treatment, constant watchfulness are sources of safety and hope to those who come under the care of a modern university hospital. The prestige of the clinical teachers who are in charge is always at stake. The mutual scrutiny of members of the teaching staff, and the alertness of students, together with unremitting search for new truth and its application to disease, make the teaching hospital the best place for the sick.

In medical education, the relation of the laboratory and clinical years is organic. The antithesis which is often set up between these two aspects of medical education is most unfortunate. In the first and second years, the chief emphasis is laid on work in the laboratories; but this training ought to be extended right into the clinical phases of the curriculum. While it will usually happen that laboratory teachers will be graduates in medicine, many able laboratory men without the M.D. degree have demonstrated their capacity to develop cooperative and sympathetic team-work with clinical departments.

As to the hospital, it is recognized that effective teaching can be secured only in an institution which is under the

complete control of the medical school. The devices of clinical clerkships, the individual responsibility of students, close relations between bedside and laboratory, the proper organization of the teaching staff, permanence of tenure, team-work, necropsy conferences, and case conferences with physicians and social service workers are all factors in the development of clinical training of the right type.

In spite of the overcrowding to which reference has been made, there is an increasing demand for the introduction in undergraduate teaching of such subjects as preventive medicine, psychiatry, institutional administration, and some knowledge of social amelioration through clinics, popular education, improved housing, better food, recreation, and the development of community responsibility. The introduction of medical sociology in the premedical course would be of distinct value.

Judged by the criteria which are suggested in this paper, existing medical schools fitting the present need fall into two general groups:

1. University centers for teaching and investigation. The chief characteristics of these institutions are: broad and thorough preparation; limitation of numbers in proportion to faculties and staff; well rounded laboratory equipment with professional teaching corps; complete control of adequate hospital and dispensary facilities with vocational leadership in the clinical departments, which include the chief specialties; practitioner or avocational clinical teachers organized systemically into a unified staff; geographic concentration of all phases of plant and instruction; laboratories and clinics in close relations of cooperation and interdependence; research a conscious purpose; facilities for graduate study.

2. Training centers, parts of academic institutions. Two-year college requirement; limitation of numbers; fundamental laboratory facilities with professional teachers; control of appointments to hospital and dispensary staff; practitioner clinical teachers well organized in long service periods; assisted by full-time resident and other assistants; concentration of buildings and work; cooperation between laboratories and clinics; some opportunity for research by staff members.

As to the policy of the General Education Board and the Rockefeller Foundation with regard to assistance to medical education, it may be said that there is no one, inflexible type of organization which it is proposed to suggest to all institutions. Aid has been given and will continue to be given to a few centers of the higher type, but assistance is also being considered with respect to a number of institutions less highly developed. The General Education Board cooperates with medical schools in the United States, while to the Rockefeller Foundation falls the opportunity to work with medical centers in Canada and in other countries.

DISCUSSION

DR. RAY LYMAN WILBUR, President, Leland Stanford Junior University, Stanford University, Calif.: Medical education is characterized in that it must be built up around a close personal relationship between the physician and the patient. In addition to the laboratory, the library and the lecture room, it requires for its development a whole group of social agencies including the hospital and the clinic. Consequently, the medical school is unique among university departments in the immediate service rendered in the solution of the day to day physical problems of the individual and of society. The whole essence of clinical teaching is to bring together the teacher, the patient, the nurse and the student in an environment most favorable for all of them. The future of medical education depends largely on the way this environment is financed and controlled. The union of the four elements is inevitable. Society, with its heavy burden of suffering, will insist on this in some form or another.

We put tens of thousands of the mentally sick into great isolated institutions, largely without medical students or training schools for nurses. Through competent administrators we care for them reasonably well, but we have learned and are learning but little of mental disease. The ignorance of the average medical man of psychology and

psychiatry is painful. Every such hospital should be a live optimistic center for study and not a pen for the lingering care of the hopeless or semihopeless. We cannot think of medical education in the future without bringing the stimulus of the student to all such hospitals, and likewise bringing one such hospital into the closest of contact with every university medical school. Perhaps with the establishment of such conditions we can gradually place the decisions on the questions of mental conditions in the hands of physicians instead of in those of untrained judges and emotional juries.

No city with a population of half a million will rest content until its medical men have at their disposal suitable hospital and other facilities for superior medical care. It is also inevitable that there will be some medical instruction wherever good medical work is done. The master in medicine needs students as much as they need a master. This does not mean a medical school in every city, but it does mean at least teaching hospitals for interns and the physicians of the neighborhood and good training schools for nurses—in other words, an educational center of prime value to the community.

Community welfare depends on the engineer and the physician more than on the politician. No physician or nurse can do his or her duty in the ordinary professional routine without training in disease from the community or public health standpoint. Every medical center, be it hospital, clinic or medical school, cannot be complete unless it offers such opportunity.

During the period immediately before us, no greater disaster could come to medical education than to have it and all of its necessary accessories fall completely into the hands of the state. The glory of American education lies in the bold initiative of such institutions as Harvard and Johns Hopkins. Picture medicine in America today had there been no Johns Hopkins, Harvard, Physicians and Surgeons of New York, or University of Pennsylvania to lead the way, so that legislatures could be stimulated to vote the money for the medical schools that have developed around the state universities. We may look ahead to a democratic state with governing bodies and a public wise enough to provide leadership in medicine; but for several generations we cannot safely trust the future of medical education with all of its needed accessories to the chances of politics.

The safety of the state university medical schools will come from the active presence of those independently endowed setting the standards in various parts of the Union. The greater burden, though, of medical education must fall on state or city controlled hospitals and universities. Through them the public will gradually learn to do its full duty in medical teaching, and in the care of patients and in research, as it is learning to spend its money to get back the return in increased production that has come from the agricultural schools.

CHARLES F. THWING, President, Western Reserve University, Cleveland: If we define education as the power to think, I think that we have a right to define medical education as the power to think in terms of medicine. I think we also have a right to say that legal education is the power to think in terms of law, both common and statute. To think is not to know simply, but it is to assess and relate knowledge. It is to know and relate fact to fact, and from fact to infer new facts. To think in terms of medicine is to think in terms of diagnosis, or understanding, of the proper evaluation of symptoms or the result of observation, each result related to every other; to assess the result of the thinking in terms of therapeutics and in terms of prognosis.

Every year at the faculty meeting in June we in Western Reserve University have this fact to contend with. We are now graduating our students at 27½ years of age. Can we get these men into the medical profession at an earlier day? We can if we will adopt the proper means; and the means lies away back of the high school; it lies in the grammar school or the grades. Boys and girls ought to enter the high school at the age of 12 and not of 14. The only way to secure that result, in my humble opinion, is not a change in the curriculum of the grammar school, but a change in the

advancing power to teach in these grammar schools; that power of advanced teaching lies in the smaller schools, the worth of the teacher lies in the element of cost, and the cost lies in the purse of the man who pays taxes. American communities ought to assess twice the present assessment in the improvement of the schools for boys and girls before the age of 12, and American communities I think are willing to do that, provided they be assured that the money is spent effectively. We are always glad to pay money in taxes for education if only the education be good. France has proved to us that their boys of 12 are as far advanced intellectually as boys of 14 in America, by reason largely of improved teaching before that age. It may be well for us in the medical school to persuade men of rather unique power to continue their education far beyond the graduation period. There are men known to every teacher who hold forth great promise. Those men should be encouraged to stay and become shepherds for the communities.

SURGEON-GENERAL WILLIAM C. BRAISTED, Washington, D. C.: We are deeply interested in the subject of medical education. We have had magnificent institutions, with full staffs of the finest type of men from the Reserve Corps. We have had perhaps the best the colleges could give us to carry on our work during the war. I feel a great degree of comfort and satisfaction in having that type of men; with the end of the war, however, we should not desist, but try to reestablish and maintain the splendid organization we had during the war. To do that we shall have to educate as quickly as possible young men for the positions of specialists. The organization I am trying to maintain is something like this: There should be an extensive laboratory. There should be specialists in operative surgery, eye, ear, nose and throat; there should be a psychiatrist, a roentgen-ray man, and the like. What I am trying to do is to have all these specialists associated and work together. For instance, in the Washington Hospital, Admiral Stitt is not only a very fine laboratory man, but one of the finest diagnosticians we have. The time has come when we in our premedical institutions should select or cull men of particular worth for work of a particular character.

SURGEON-GENERAL M. W. IRELAND, Washington, D. C.: Medical education is of the greatest importance to us. Very early in the history of the Medical Department of the Army the Surgeon-General called attention in his annual report to the better class of men we were getting. Away back in 1840, the Medical Department of the Army had something to do in creating a better and higher standard for students who were studying medicine. In the last twenty years, medical men have been coming into the Medical Department of the Army at the average age of 28. They should enter earlier in life. In many of our army hospitals we can now give good training in diseases of women and children, as well as in the other departments of medicine. We will take men from medical colleges and give them certain compensation in addition to their upkeep while in the hospital. That is the proposition we have to present to young graduates in medicine who come into the Medical Department of the Army to complete their hospital experience.

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.: Dr. Bevan, if I understood him correctly, spoke rather slightly of the showing that the civilian medical profession made in the war, particularly the laboratory men. I am not going to say a word about what the clinicians did in the war. When Surgeon-General Gorgas wanted me to formulate rules for the sterilization of water in all camps in the army, to whom could I turn? I summoned three men to Washington—Whipple, Sedgwick and Phelps, not medical men but laboratory men—men skilled in preventive medicine. I do not believe any one of them has a medical degree. These men formulated rules and gave details for the sterilization of water in all the camps and in all the field hospitals. It was done in three days. The chlorination of water was decided on.

We are building a hospital now in Ann Arbor that will have 800 beds; but this is a relatively small part of the hospital. Most of it will consist of laboratories for professors

of bacteriology, pathology, clinical medicine, scientific medicine, chemistry, etc. There is no one who has greater admiration for the surgeon and the clinician than I have, but it does seem to me that we overlook sometimes the valuable services rendered by the laboratory men to the surgeon and clinician. The pathologist, the chemist and the bacteriologist are just as important in their respective fields as the man who gives medicine or uses the knife.

DR. H. GIDEON WELLS, Chicago: I have been authorized to read into the minutes of this joint conference the resolutions passed by the National Research Council, composed of both clinicians and laboratory men:

WHEREAS, A committee composed of Drs. Erlanger, Jackson, Lusk, Thayer and Vaughan appointed by the Division of Medical Sciences of the National Research Council to study the situation in regard to the supply of assistants in preclinical departments have made a thorough study of conditions in the medical schools of the country and submitted a report setting forth existing conditions and analyzing suggestions as to improvements; and

WHEREAS, This study shows that there is a serious scarcity of men of proper caliber for assistants in preclinical sciences seeking such positions; be it

Resolved, By the Division of Medical Sciences of the National Research Council:

1. That this deficiency in assistants constitutes a very serious menace to medical education because not alone are there insufficient assistants for the present needs of instruction in the preclinical sciences, but the deficiency of the present inevitably must result in an inadequate number of men qualified for higher positions in the preclinical sciences and a consequent deterioration in these departments in a very few years.

2. That since the clinical departments are in many ways dependent for their efficiency on the instruction afforded and the investigation conducted in the preclinical sciences, deterioration in the preclinical sciences will result in deterioration in the clinical departments.

3. That since these conditions enumerated under 1 and 2 exist, it is very essential that steps be taken to provide for a more satisfactory supply of assistants in the preclinical sciences.

4. That since directly or indirectly the remedy for these conditions depends to a large degree on increased budgets for salaries for assistants, instructors, assistant professors and professors, technicians and supplies, it is highly important that funds be secured for these purposes to prevent deterioration in the entire structure of medical education.

5. That, since this need for funds for the preclinical sciences seems so pressing, the larger proportion of funds available for developing medical education should be applied to the preclinical rather than to the clinical departments of the medical schools for the present and until such time as a more satisfactory situation is obtained in the preclinical sciences.

DR. LOUIS B. WILSON, Rochester, Minn.: I should like the privilege of supporting these recommendations of the Council on Medical Research. Since Jan. 1, 1919, I have had 1,121 applications for fellowships in the Mayo Foundation. Four were for work in the fundamental sciences. This is not the general ratio. So far as we can determine, there are in the United States today not one-fourth as many young men engaged in laboratory work as there should be to fill the places which are now vacant.

DR. GEORGE M. KOBER, Washington, D. C.: We are all proud of the achievements in scientific medicine in the United States which have been brought about very largely through experimentation on the lower animals in determining the causes, prevention and treatment of disease. A bill has been introduced in Congress, known as Senate Bill 1258, and in connection therewith I wish to present the following for adoption:

The Annual Congress on Medical Education, composed of the Council on Medical Education of the American Medical Association, the Association of American Medical Colleges, and the Federation of State Medical Boards of the United States, has learned with regret that serious efforts are being made to enact Senate Bill 1258, "A bill to prohibit experiments upon living dogs in the District of Columbia and in any of the Territorial or Insular Possessions of the United States."

The highest aim of scientific medicine is the eradication of preventable diseases. The average span of life in the United States has been lengthened fully eight years during the past twenty-five years, largely the result of animal experimentation in the study of the causes, prevention and treatment of communicable diseases.

A careful examination of the law now in force in the District of Columbia shows that the provisions of the current law are ample and sufficient to prevent cruelty to animals, and since the enactment of the bill would be the death knell to the progress of scientific medicine, this congress respectfully but earnestly protests against its enactment as unnecessary legislation and detrimental to the best interests of the human family, and to animal husbandry.

The resolution was put to a vote and adopted unanimously.

Arithmetical Computation of Roentgen Dosage. G. M. MacKee, New York.—p. 602.
Treatment of Diseases of Thyroid; So-Called Hyperthyroidism. J. A. Lichty, Pittsburgh.—p. 608.
Treatment of Goiter by Radiation. R. H. Boggs, Pittsburgh.—p. 613.
*Early Roentgen-Ray Diagnosis of Ulcerative Tuberculous Colitis. L. Brown and H. L. Sampson, Trudeau, N. Y.—p. 625.
Teleroentgenography of Head. P. M. Hickey, Detroit.—p. 641.
Safety Device for Roentgen Ray Tubes. G. C. Johnston, Pittsburgh.—p. 643.
Multiple Myeloma of Bones. W. A. Evans, Detroit.—p. 646.

Dislocation of Innominate Bone.—A boy, aged 6 years, fell from the seat of a farm wagon loaded with 3,200 pounds of coal, and the front wheels passed over his abdomen. Shock and prostration were marked. The patient could not be moved for ten days. The leg was flexed and the foot was everted. A large hematoma covered the entire lumbar region. The roentgen rays revealed a dislocation of the left innominate bone. Attempted reduction failed; fixation in plaster for three weeks brought about recovery with normal function.

Early Roentgen-Ray Diagnosis of Ulcerative Tuberculous Colitis.—While in many cases of ulcerative tuberculous colitis a positive diagnosis by clinical or laboratory methods cannot be made, Brown and Sampson claim that the roentgenologic method has enabled them to make a diagnosis positively in many cases in which otherwise the diagnosis would have remained uncertain. The roentgenologic diagnostic criteria are filling defects and hypermotility.

*Yellow Fever Observations Made in Guayaquil, Ecuador, in 1918. C. A. Elliott, Chicago.—p. 174.
*Pericarditis with Effusion. An Experimental Study. C. S. Williamson, Chicago.—p. 206.

Study of Colloidal Gold Reaction and Its Clinical Interpretation.—While Warwick and Nixon believe that the colloidal gold test is the most delicate of the routine spinal fluid reactions, it does not replace any other test but, on the other hand, is of independent value. It is of especial importance in the early diagnosis of neurosyphilis. A colloidal gold curve may be obtained with or without other positive findings after provocative treatment. It does not parallel clinical signs nor give definite evidence of improvement under treatment. Patients with no involvement of the central nervous system, or who are nonsyphilitic, give no colloidal gold curve. Clear cut clinical cases of tabes dorsalis may show all the spinal fluid reactions negative both before and after treatment. A curve in Zone III, with a negative cell count and negative or faintly positive globulin, is strongly suggestive of a brain or cord tumor or myelitis. Curves in Zones I and II may be found in nonsyphilitic conditions, such as multiple sclerosis and brain abscess. A cell count above five is pathologic, but the cell count is of no value in indicating duration or severity of the process or improvement. The authors recommend that this reaction should be included in every spinal fluid analysis and neurologic examination as well as in all cases of general syphilis.

Yellow Fever in Guayaquil, Ecuador, in 1918.—The clinical and pathologic findings are summarized by Elliott from a study of about seventy cases of yellow fever observed in Guayaquil, Ecuador, during the summer of 1918. Clinically, yellow fever is similar to infectious jaundice. The differ-

ences existing between the two diseases appear to be chiefly those of degree. There is more marked jaundice and less hemorrhage in yellow fever than in infectious jaundice. Although hemorrhage is a usual occurrence in all severe cases, yellow fever is not a true hemorrhagic disease. The hemorrhage apparently follows necrosis of parenchymatous tissues and endothelial cells. The jaundice of yellow fever appears to be of a nontoxic dissociated, hepatic (suppression) type. Death appears to be due to uremia. It is usually preceded by anuria. There is an intense degeneration of the epithelium of the convoluted tubules. The glomeruli and collecting tubes remain relatively free from degeneration. Convalescence in all patients who survive is prompt. The complete restitution of all organs to normal is remarkable. No evidences of impaired liver or kidney function remained in the cases studied, although Elliott says that intense parenchymatous changes must have occurred. Many cases are analyzed.

Pericarditis with Effusion.—By means of experimental research, Williamson found that in pericardial effusion the fluid accumulates first along the lower margin of the heart and about the apex, particularly on the diaphragmatic surface of the heart. With small effusions, this is the only place in which fluid accumulates with regularity. The result of the accumulation of the fluid in this position is to push down the left lobe of the liver. This was demonstrable in practically every case, and in many cases it was a very conspicuous feature. Special stress should be laid on this as an early diagnostic sign. The second place in which fluid accumulates is over the great vessels at the base. With small effusions it is occasionally present in sufficient amount to be detected by percussion. With medium sized effusions this layer is generally thick enough to be demonstrable by percussion, and this retrosternal dullness is an important diagnostic sign. With both small and medium sized exudates Williamson was unable satisfactorily to demonstrate percussion dullness in the fifth right interspace (Rotch), nor could a rounding of the cardiohepatic (Ebstein) angle be made out in a single case. The behavior of the fluid is practically independent of the position of the patient. In at least fourteen of the thirty-three cases studied the anterior surface of the heart, in spite of the exudate, remained, in part, uncovered by the fluid so that a pericardial friction rub could readily exist. This pericardial rub is to be anticipated in cases in which the heart is relatively large, so that it fills out the space between the vertebral column and the sternum. From the standpoint of the most readily reached small amounts of fluid, the most appropriate sites for puncture are either just outside the apex or in the chondroxyphoid angle.

System in Care of Sick. R. D. Rudolf, Toronto.—p. 185.

Winnipeg Epidemic of Lethargic Encephalitis.—In the Winnipeg epidemic of sixty cases there were twenty-three deaths, a mortality of 38 per cent. The characteristic case presented fever, drowsiness, strabismus, ptosis, diplopia, tiinitus, some degree of facial weakness, constipation and,

perhaps, some urinary and spinal fluid changes. The fleeting nature of the disturbances was very typical. Sensory disturbances were present in a number of cases. Some of the cases were atypical, suggesting cerebral tumor, apoplexy and other brain lesions. The brain was examined in eighteen cases, and showed marked congestion, perivascular infiltration with lymphocytes and plasma cells, and occasionally hemorrhage. Degeneration of the nerve cells was variable. The changes were most marked in the midbrain. Marked lesions were also found in the kidneys. A remarkable epidemic of hiccup occurred in Winnipeg at the same time as the outbreak of encephalitis.

Sterilization of Oils by Means of Ultraviolet Rays.—Experimental research by Fairhall and Bates has shown that certain oils, such as olive oil, cottonseed oil and almond oil,

can be sterilized effectively by means of relatively short exposure to ultraviolet rays. The abiotic power of the ultra rays is not restricted to the vegetative bacterial cell alone but extends to the spores as well as to certain molds, such as *Penicillium*, *Aspergillus* and *Mucor*. Lipolytic enzymes in oil are sensitive to, and their action is inhibited by, exposure to ultraviolet rays. Except for a slight bleaching, the oil is unchanged physically and chemically by this exposure. The sterilizing effect of ultraviolet rays is still apparent after they have been filtered through layers of oil 4 mm. in thickness. Olive oil when exposed for long periods of time shows an increase in acidity, and this increase is directly proportional to the length of exposure.

Bacillus of Morgan No. 1: A Metacolon Bacillus.—Nine cases of diarrhea or dysenteriform colitis are analyzed by Thjøtta. Two of these ended fatally and the postmortem examination showed the existence of a severe colitis. From these cases of intestinal disturbance, typical strains of the bacillus No. 1 of Morgan were isolated, while it was impossible to discover the presence of other pathogenic germs. Seven of these strains were studied immediately after isolation as well as after one and one-half years of growth on artificial mediums, and most of them altered their characters considerably during this time. They could culturally no longer be recognized as belonging to the Morgan group, but had to be looked on as dysentery strains. Serologically, there could not be detected any relation between these strains and other pathogenic microbes, such as typhoid, paratyphoid A and B, dysentery I, II and III or colon bacilli. Neither was it possible to find any considerable relation between the various strains themselves, nor did any of the strains show the slightest agglutination in the serum from the patients. Thjøtta concludes that the Morgan bacillus is simply a *Bacterium coli* of a certain fermenting type. Consequently, he says, it would be better to give it the Danish name "metacolon organism" as this name points to the large group of the colon bacilli, while the name of Morgan bacillus gives the idea of a microbe of a certain special type.

Methods of Isolation and Identification of Members of Colon-Typhoid Group of Bacteria.—According to these authors the bactericidal power of CR (China blue-Rosolic acid) is due entirely to the action of rosolic acid. Moreover, the inhibition of growth seems to be directed only against gram-positive bacteria. Almost all gram-negative bacteria tested grow readily on a medium containing twenty-five times the amount of rosolic acid which is inhibitive for gram-positive organisms. This apparent selective action of rosolic acid, coupled with its failure to inhibit the growth of *B. dysenteriae* renders this dye particularly suitable for the preparation of selective mediums to be used for the isolation of intestinal bacteria.

Extracts of Pure Yeast for Culture Mediums.—The value of using extracts made from dried pure yeast, that is, yeast which has been washed and then dried at a low temperature without the addition of starch or other fillers, is emphasized by Ayers and Rupp. This extract may be used alone as a basis for more complicated mediums when necessary. Extracts of pure yeast contain, besides amino-acids and other proteins, fermentable material in small amounts, probably present in the yeast cell which makes them valuable for general bacteriologic purposes. The fermentable material probably stimulates growth but renders the extract valueless as an ingredient of mediums for fermentation tests.

*Relation of Inbreeding to Tumor Production: Studies in Incidence and Inheritability of Spontaneous Tumors in Mice. M. Slyce, Chicago.—p. 53.

Pathologic Changes Accompanying Injections of Active Deposit of Radium Emanation.—Gagg claims that following

injections of an "active deposit" of radium emanation there is a diffusion of the radioactive substance throughout the animal body, which results in pathologic changes in the various organs. The most interesting changes were those that were found in the liver, and resulted from comparatively small doses of radium injected subcutaneously. A fatty degeneration, associated with many giant cells and hyperchromatic nuclei, was found in the liver for a comparatively long time after the treatment. Following large doses of radium, congestion and hemorrhages were frequently found in practically all the organs and in the severe, acute cases the animals died after showing symptoms of marked enteritis. The most frequent pathologic condition that occurred in the kidney was a granular degeneration and erosion of the renal cells. It was found that injections of radium resulted in the destruction of the cells of the bone marrow, and replacement by blood. Congestion of the spleen was the most constant feature following radium treatment, and in some cases this was associated with hemorrhages, and the destruction of red blood cells. The method of injection appears to determine, to a certain extent, the severity of reaction in certain organs. For example, following subcutaneous injections there was comparatively no pathologic reaction, of an appreciable extent, in the lungs, but with intravenous doses, of about the same strength, the lung lesions were severe, and consisted of proliferation and desquamation of the epithelial cells of the bronchi, marked edema, congestion and hemorrhage. The results of this investigation tend to show that the liver, gastro-intestinal tract, kidneys, lungs and spleen receive the greatest amount of radioactivity.

Relation of Inbreeding to Tumor Production.—Inbreeding is demonstrated by Slye not to be an influence in the increase or the incidence of cancer, but merely a method of analyzing a strain. Strains consistently inbred may produce 100 per cent., or 50 per cent., or 0 per cent. of cancer according to how much cancer is bred in, not in accordance with the method used. The real effect of inbreeding is to eliminate cancer by eliminating the strain. It is hybridization which increases cancer by increasing the output of cancer progeny. The ratio of tumor "takes" in increasingly later generations from hybrid crosses of low grade productivity, proves nothing, Slye claims, with reference to the inheritability of cancer, but demonstrates the biologic relation between race vigor and the number of tumor "takes." As the cancer ancestry behind a generation broadens and deepens, the individuals of that generation tend to run more and more to cancer production. This is equally true of inbred and of hybrid generations, since the amount of cancer which comes out in the progeny depends on the amount which is put into the ancestry, whether the method is inbreeding or hybridization. It is, therefore, possible wholly to eliminate cancer from the race by not putting it in through the ancestry; this is true both in inbreeding and in hybridization. In demonstrating the inheritability of cancer and of other tumor types in mice, Slye has demonstrated their inheritability also for man and for every other species in which they occur, since the cancer and noncancer tendencies which segregate out in mice must segregate out also in every other species in which they occur, and this is the test of heredity.

Tropical Sprue in New York.—Two cases of sprue seen in New York are reported by Sturtevant. One of the patients had been in Havana and the other had been in Florida for a few weeks each winter. Both the patients had symptoms

of sore mouth and diarrhea, coming in attacks. They had both lost weight. Both had a curious earthy color to their skin. Their stools were largely fat with normal pancreatic ferments. They responded in striking manner to milk diet. One of the patients showed characteristic improvement on strawberries. The other patient found the addition of salt to his milk made the milk more palatable and developed a sort of salt hunger or craving so that he would take from 40 to 70 gm. or more of sodium chlorid in twenty-four hours.

Syphilitic Heart Disease. C. M. Grigsby, Dallas.—p. 368.

Gumma of Trachea.—The symptom for which Israel's patient came to the hospital was a severe attack of dyspnea. On examination, a swelling about the size of a hen's egg, was found in the upper third of the trachea. The blood Wassermann was ++++ positive. Under antisyphilitic treatment, arsphenamin injections and potassium iodid, the mass seemed to melt away. Only a slight thickening remained.

Fetish of Central Ray. M. Berrý.—p. 264.

Roentgenotherapy of Uterine Fibroids.—In 400 cases treated by Bécélère with the roentgen ray, the two principal results obtained have been the suppression of the metrorrhagia and the reduction in the volume of the tumors. He believes that radiotherapy of uterine fibroids is one of the most important of the uses of roentgen rays in the treatment of neoplasms. Its principal rôle is to induce the destruction and disappearance of the neoplastic cellular elements of which the fibromas consist; this is the direct effect of this form of treatment, and is the earliest manifestation of its action. It is, however, nearly always necessary to continue the radiations up to the point of the destruction of

the normal cellular elements of the primitive ovarian follicles. When the treatment is suspended after the cessation of the periods, and the appearance of the hot flushes which characterize the menopause, the uterine tumors usually continue to decrease, sometimes much more slowly than during the treatment. But, if, after a more or less long interval the periods reappear, this return is very frequently accompanied by a revival of the activity of the fibroid, and it again increases in size. Bécélère recommends that patients, especially those under the menopause age, should not wait until the periods return before they resume treatment, but that they should submit themselves for a fresh examination if the hot flushes prematurely cease. In a similar manner the discovery that the uterine tumor has increased in size is an indication for the immediate resumption of the treatment.

Roentgen-Ray Treatment of Case of Early Acromegaly.—In acromegaly, roentgen-ray treatment at present rests almost entirely on a theoretic basis. Webster contends that it should be eminently a disease suitable for roentgen-therapy, especially in its early stages, when the anterior lobe of the pituitary would show merely a simple chromophil hyperplasia, and before secondary tumor-like formation, local pressure damage, and much skeletal change has been produced. In his case so treated the disease had been of almost four years' duration. She had sixteen treatments with hard filtered rays from temporal and frontotemporal areas, the first eleven at weekly intervals, then fortnightly, latterly at monthly or longer periods. The effect was remarkable. The severe headache was rapidly relieved, and soon entirely disappeared. The "queer feelings" almost entirely left her: from two or three weekly they dropped to about one a month. The irritability and depression almost completely left her. She lost about seven pounds in weight. The most striking changes were in the eyes, the optic discs returned practically to the normal, while the fields of vision (especially for red) greatly enlarged. The right eye still presented some irregular contraction, chiefly inferior temporal. Apart from one or two bromid powders there was no treatment beyond irradiation. The patient was lost sight of for nearly two years; her condition, subjectively and objectively, had become aggravated again. She was then operated on successfully by the nasosphenoidal route.

*Lymphangioma of Tongue. B. W. Howell.—p. 213.
*Case of Leukoderma and Melanoderma Associated with Leukonychia. H. C. Samuel.—p. 217.

Sequel of Lipodystrophia Progressiva.—It is claimed by the authors that this seems to be the first published post-mortem examination of a case of lipodystrophia progressiva. The patient, a girl, aged 13 years, was operated on for a purulent otorrhea. Soon afterward there developed a septic type of pyrexia. The patient died about three months after operation. In the sections of the scalp and abdominal wall, the only evidence detected of fatty tissue was the presence in the scalp of a few small areas which may have been occupied by fat cells. One of the sections of the suprarenal bodies included a little of the surrounding retroperitoneal tissue. Definite fatty tissue was present in this. In no section were there lobules of embryonic fatty tissue such as are found in the fetus, and in infants during the first and even second year of life. No abnormality was detected in the ovary. In the suprarenal bodies there appears to be less lipoid than usual in the cortex. In the thyroid glands there was an excess of secretion of colloid. The authors consider it reasonable that such a pathologic condition of the thyroid was connected with the abnormality in the subcutaneous fat.

Lymphangioma of Tongue.—Howell's patient was only 6 years old. There was no family or personal history of disease. He gave a negative Wassermann reaction. He had congenital nevus of the lower lip, which involved the mucous membrane of the gum. This got fuller when the child cried,

and bled occasionally. The swelling of the tongue was first noticed when the child was 3 years of age. It commenced on the posterior aspect and had grown forward slowly. It became stationary, vesicles continually broke down and ulcerated, causing pain, and on that account the boy bolted his food, which was always minced. He ate most things and took a rather large amount of salt, of which he was fond, but avoided sauces. Occasionally, the tongue was enlarged without apparent cause, and protruded from the mouth. It was then excessively painful, and was a source of anxiety to the patient and his parents. Salivation was excessive and articulation impaired. The tonsils were much hypertrophied, the submaxillary lymphatic glands were much enlarged, and the submental glands were palpable.

Case of Leukoderma and Melanoderma Associated with Leukonychia.—A boy, aged 6 years, presented in the left lower costal and lumbar regions a melanodermic sheet on which were small leukodermic spots arranged in lines. On his nails were some early spots of leukonychia. The elder brother also exhibited the early stages of leukonychia striata on several of the finger nails. The father had recently developed well marked leukoderma and melanoderma at the angle of his lower jaw, and some leukonychia of his fingers. The father's brother had every well-marked leukonychia striata of all his finger nails.

 *Simple Treatment of Ringworm of Nails. R. Craik.—p. 185.
 Mode of Infection in Pulmonary Infection. T. Campbell.—p. 185.

Tumors Complicating Pregnancy, Labor and Puerperium.—It is Spencer's belief that the great majority of cases require only careful supervision during pregnancy, periodical examination of the urine, rest, mild aperients and anodynes if the tumors become painful. Induction of abortion, premature labor and forcible delivery past obstructing tumors are contraindicated. Forceps may be required for inertia but should never be used to overcome resistance caused by tumors. Craniotomy and embryotomy are called for only in cases in which the fetus is dead and the mother not affected. Polypi and pedunculated subperitoneal tumors should be removed. Vaginal myomectomy may be required for cervical fibroids, but should not be performed for retrocervical tumors. Abdominal myomectomy is rarely needed, and usually only for very large or twisted or necrobiotic tumors. It not infrequently leads to abortion and to hysterectomy in order to stop the hemorrhage from the bed of the tumor, and it often fails to remove all the tumors present in the uterus. Before performing myomectomy, as also before conservative cesarean section, the tumor should be examined bacteriologically, and if it is infected, the whole uterus should be removed. Hysterectomy during early pregnancy, in the absence of hemorrhage or infection, is rarely called for. Conservative cesarean section is rarely indicated by the fibroids alone, but may be performed when fibroids are associated with contracted pelvis or malpresentations of the child, especially in elderly primiparae. In the case of a single myoma, it might be possible to remove the myoma and child through the same incision. In the puerperium, vaginal myomectomy is usually the best treatment for submucous tumors even when they are infected or invert the uterus. It should usually be tried before resorting to hysterectomy, which Spencer has never found to be necessary. In infected subperitoneal or intramural tumors total abdominal hysterectomy should be performed.

Penetrating Wound of Chest; Thoracotomy; Suture of Pericardium.—Haycraft regards his case as of interest as throwing light on the question whether it is necessary to close a large traumatic communication between the pericardial and pleural cavities. He was obliged to suture a

tear in the right lung at the lower part of the junction of the anterior and basal borders, with fine linen thread, and a tear in the pericardium about 2 inches in length from above downward, through which was protruding the right auricular appendix and part of the right auricle. This was closed by a continuous suture of fine linen thread, but with considerable difficulty, owing to the extremely rapid beating of the heart and the attempts of the auricular appendix to get outside the pericardium at each beat.

Treatment of Ringworm of Nails.—In the two cases cited by Craik, the disease had existed for months in one patient, for years in the other. They were given a lotion consisting of 1 dram of salicylic acid in 1½ ounces of methylated spirit, to be painted on after scraping every night, and without scraping every morning, and to be used for three months or longer. Both patients were cured.

Modified Silver Method of Staining Cilia and Spirochetes.—Hidaka makes use of silver in the form of an ammonium salt. Not only the cilia of the typhoid bacilli and allied bacteria, but also spirochetes and the cilia of cholera vibrios take the stain very easily. The following solutions are employed: (A) 100 parts of a 10 per cent. acetic potassium solution; (B) 100 parts of a 3 per cent. phenol solution; 10 parts of tannic acid; (C) 20 parts of a 2 per cent. stibio-kalium tartaricum. Solution A is put in a 200 c.c. flask and heated at 40 C. While heating, solution B is poured into the flask and heating is continued until the white precipitate is completely dissolved. Solution C is then added; a thick white precipitation occurs. This cloudy solution is the required macerating solution and may be used without being filtered. The solution thus obtained is stored in a brownish dripping bottle and is shaken before use. The residue is more efficacious than the filtrate. This residue may be desiccated and the dried substance may be employed by dissolving in water. This solution is poured over the entire surface of the smear to be stained, and is heated over the flame until vapor arises from the surface of the fluid, which becomes granular in appearance. Usually from one-half to one minute heating will effect this. Then the smear is washed with water. The ammonium silver is poured over the smear and heated; washed in water. Ammonium silver solution is prepared as follows: Ammoniac water is poured into a 3 per cent. silver nitrate solution enough to effect the dissolution of all the precipitate that is formed by the adding of the former for the first time. Then the 3 per cent. silver nitrate solution is dropped into the mixture until it turns cloudy. The mixture thus prepared is stored in a brown bottle. The bacterial bodies appear black and the cilia dark brown.

"Bone Setting" Forced Movement.—The whole subject of treatment of after-effects of injury, Mennell says, is interwoven with that of the administration of forced movement, and this in turn is intimately connected with the art of what is commonly known as "bone-setting," and until the time has come when the old teaching of absolute and prolonged rest after injury shall have been supplanted by Lucas-Championnière's doctrine of the scientific combination of rest with mobilization, the type of disability which fills the "bone-setter's" rooms will never disappear. The first golden rule in manipulation under anesthesia should, therefore, be that no further attempt at movement is to be made in any direction when once a definite adhesion has been felt to give way. If this rule is ignored, injury will inevitably be inflicted on the fibrous tissue which forms a large bulk of the muscles which oppose the movement. Movement in other directions may, however, be continued. Mennell discusses the choice of time anesthetic and technic, the general procedure and the movement used for individual joints in detail.

Hydatid Disease of Bone.—In Corlette's case hydatid cysts were found in the femur, the right pelvic bones and the thigh, reaching from the level of the upper end of the bone above nearly to the popliteal space below; between the spleen and the diaphragm, the top of the spleen forming its floor, and the under surface of the diaphragm forming its roof. The kidneys and liver were entirely free from any sort of hydatid growth or deposit. So was the left lung. But the right lung presented a very remarkable appearance. The whole of the apical part looked like marble, giving the impression that a series of small hydatid cysts were lodged beneath the pleural surface. At the lower margin of the upper lobe another hydatid mass could be seen, about the size of a pigeon's egg and elastic in consistency. This was incised and found to contain a densely packed mass of crumpled looking hydatid membrane, cutting like a solid jelly. No free fluid exuded from the section, and there was no sign of an enveloping mother cyst. The brain was not examined.

Cases of Intestinal Obstruction.—Perry cites a case of atresia of the small intestine discovered in a child eighteen hours after birth. The small intestine ended blindly. Enterostomy was performed but the child died after six hours. A second case was one of strangulated sciatic hernia in a woman, aged 27, who was eighteen weeks pregnant.

Cases Treated by Roentgen Rays, Radium and Electrotherapeutics. de V. Hugo.—p. 4.

Poisoning of Cooper's Dip. P. H. Walker.—p. 12.

Agar: A Fluid Medium.—Pijper maintains that the so-called water of condensation found at the bottom of agar slants and on the surface of agar plates is not water and not merely the product of a process of condensation. This so-called water of condensation, Pijper says, ought to be called agar serum, and it is mainly the product of a process of secretion caused by the syneresis of the agar gel. The micro-organisms planted on the medium are bathed in this agar serum, which provides them with nutrient substances. Agar mediums, therefore, are not solid, nor simply liquefiable mediums, but they are fluid mediums, in which the

production of the fluid available for the nutrition of the microbes proceeds very slowly and follows certain rules. The secretion of this serum, and the concentration of its constituents, and therewith the value of an agar medium from a bacteriologic point of view, are dependent on various factors, which ought to be investigated.

*Artificial Eyes in Antiquity. Van Duyse.—p. 262.

Clinical Examination in Disease of Nervous System. M. Molhant.—p. 27. Conc'n.

Serotherapy of Tetanus.—Stassen and Voncken emphasize that the fear of serum sickness and even the development of serum accidents should not deter from pushing the anti-serum treatment in tetanus, both by the intraspinal and the subcutaneous routes, as in it lies the only hope of influencing the disease.

Artificial Eyes in Antiquity.—Van Duyse recalls that no authentic specimen of an artificial eye supposed to have been worn by a living person has been found in the excavations in Egypt. But the marble and glass, terra cotta and enamel eyes found in mummies and in funeral masks are indirect testimony in favor of the ancient Egyptians having known and used prostheses for the eyes, as they were so particular about their appearance.

*Vaccine Therapy of Osteomyelitis. R. Grégoire.—p. 41.

Clinical Examination of the Constipated. J. Gènevriér.—p. 42.

Vaccine Therapy of Acute Staphylococcus Osteomyelitis.—Grégoire warns that time should not be wasted on vaccine therapy when septicemia has undetermined the system so that it is unable to respond to the stimulus of the vaccine. Even when the general aspect is good, he does not persist with the vaccine if the fever does not show signs of abating in forty-eight hours. The abscess should not be opened, as this invites secondary infection. Even very large swellings subsided completely under the vaccine treatment; in three cases he punctured to relieve the distention. His experience has not indicated that any better results are obtained with large doses than with small, while there may be disagreeable reactions to the larger doses, especially on the part of the heart. The pulse always ran up, sometimes to 140 or 150, but without disturbing the patient, and it kept high for two, three or four days. He never ventured a new injection until the pulse had returned to its former rate. Nine cases of acute or subacute osteomyelitis have been treated in this way, beginning with a stock vaccine; sometimes the abscess was punctured two or three times before the final complete retrogression. Some of the patients recovered without hyperostosis, and it never amounted to much. From two to nine injections were given in the different cases, and the total of 400 millions was never surpassed. The cure was complete in five or six weeks and the general condition was far better than in the surgical cases.

*Malaria and Amebiasis. E. Joh and L. Hirtzmann.—p. 1139.

Onabain in Cirrhosis of Liver. H. Dufour and G. Semelaigne.—p. 1143.

Congenital Senile Skin.—Variot and Cailliau state that the corrugated senile skin in the case reported was noted at birth, while in cases of geromorphism that have been published by others, the senile aspect of the skin developed in the children later, after several years of a normal aspect.

Spirochetal Jaundice with Rash.—Garnier and Reilly say that a scarlatiniform rash preceded the jaundice in a case they relate. The young civilian recovered completely in

about a month. The urine contained the spirochetes, confirmed by inoculation of guinea-pigs but agglutination tests were negative. The differential diagnosis was difficult as the symptoms for five days were merely gastro-intestinal disturbance, fever, depression and myalgia, headache and herpes, and then came the rash. As this became generalized, the eyes showed the tendency to jaundice. There was no desquamation later, and the assumption of superposed scarlet fever has no basis.

Measles and Transfusion of Blood.—Terrien found that the infant of 13 months was developing a malignant form of measles. The rash lasted only one day, and the most vigorous measures, including mustard packs, failed to bring it out again. The child's strength was kept up with camphorated oil and daily glucose-epinephrin injections. The condition growing constantly worse, a subcutaneous injection was made the fifth day of 20 c.c. of whole blood from a brother who had had measles six months before. By evening the infant was playing in its bath, and he slept that night for the first time. The temperature began to go down, and by the next day the child was cured. Terrien emphasizes the rapid improvement after this plasma-therapy, the efficacy of the subcutaneous route for infants, and the fact that the antitoxins had persisted for six months in the donor. The subcutaneous route avoids the danger of the shock from intravenous administration, and it also renders unnecessary any preliminary testing of the donor's blood for hemolytic properties.

Erosive Angina.—Harvier has encountered three cases recently which do not fit into the frame of any known type of sore throat. The infectious process affected only the anterior pillar, and only on one side. The oval lesion is more an erosion than an ulceration, and there is no false membrane formation, but the onset is febrile and stormy, and the glands nearby show slight congestion. The lesion does not spread, but it lasts for three weeks and then subsides, regardless of the local measures applied. Bacteriologic tests showed cocci and an occasional staphylococcus.

Malaria and Amebiasis.—Job and Hirtzmann comment on the puzzling character of the sickness when amebiasis is associated with malaria. Proper treatment is extremely important as emetin will cure the one and quinin the other, or at least this will attenuate them, as a rule. In some cases, however, the intestinal or liver amebic disease complicated with malaria proves inevitably fatal.

*Minor Displacements of the Vertebrae. E. C. Cyriax.—p. 457.

*Tuberculous Lesions in Temporal Bone. Bellin, Aloin and Vernet.—p. 486.

*Ligneous Phlegmons. S. Mercadé.—p. 499.

*Buried Shoe-Lace Suture. W. Dubreuilh.—p. 509.

Minor Displacements of Cervical Vertebrae.—Cyriax' experience with hundreds of cases of incomplete dislocation of the cervical vertebrae has confirmed its unsuspected frequency, and that it can occur without any symptom, although usually it causes more or less disturbance analogous to similar minor displacements in the bones and cartilages of the limbs. The pathology and the necessity for reduction and the technic for the latter are practically the same in all. The pain, stiffness, and inability to move the head may all disappear as compensation becomes established. In one of his cases there were no functional symptoms except change in the voice, rebellious to all treatment. Palpation in the dorsal position is most instructive. One transverse process in front, the other at the back, signifies rotation on the axis; one in front, with the other in normal position, signifies rotation with unilateral forward displacement. He lists the other displacements liable to be encountered, with radiograms of each, and four typical case histories. The displacement can generally be reduced by the appropriate maneuvers with little or no pain.

Tuberculous Lesions in Temporal Bone.—Bellin and his co-workers have encountered four types of tuberculous osteitis in the temporal region and ear, and cite a fifth type

described by Bernard. They give an illustrated description of a case in each type: (1) latent tuberculous mastoiditis, often revealed by deafness; (2) tuberculous mastoiditis with necrosis, sometimes revealed by facial paralysis; (3) the same with fistulas; (4) chronic osteitis of the middle ear with hyperostosis of the mastoid, and (5) osteitis of the auditory meatus or of the scala tympani. The cases reported terminated fatally, the mastoid lesion being usually accompanied with tuberculous lesions elsewhere. The only exception is a case in which the outcome is not known although the immediate results of a radical operation were good. The lesion seemed to be limited to the external meatus and scala tympani, except where the condyle of the lower jaw had been touched by the osteitis. As a general rule, reliance must be on general measures until we can learn to detect these processes in their incipency and remove the focus before there is extensive destruction.

Woody Phlegmon.—Mercadé is confident that some foreign body is the primary factor in a ligneous phlegmon. Medical measures have always failed, and there is scant hope for resorption until the tumor with its foreign body has been excised. The incision can be sutured at once and the cure is complete in a few days, unless the phlegmon has assumed such dimensions that its entire removal is impracticable. In the ten personal cases described, the phlegmon was on the thigh, forearm, buttocks or neck, and it had developed after a war wound.

Buried Shoe-Lace Suture.—Dubreuilh uses very fine catgut and an extremely curved needle, and sutures the deeper layers of the incision together, the course of the threads exactly like the lacing of a shoe. The stitches must be as close together as possible—less than 1 cm. apart—as the threads cross and recross each other. To ensure even coaptation he ties the threads together at every fourth or fifth stitch. In three or four of the 100 cases in which he has applied this shoe-lacing suture in operations on the face, the catgut was cast off; in a few others the lips separated anew but only for a short distance, thanks to the relay knots. On the other hand, the superficial sutures have sometimes suppurred, especially in operations on the mouth, but the buried shoe-lacing suture held. This suture is a little more tedious than others but it interferes less with the circulation, and has several other advantages for operations on the face.

Roentgen-Ray Treatment of Uterine Fibromyomas.—Bécclère's communication supplements his previous one at the London medical congress in 1913. He now has a record of 500 cases of uterine fibromyomas treated by irradiation, and the interval since in 400 of the cases has been long enough for a decisive verdict. In 84.5 per cent. of the cases the fibromas projected into the abdomen from 1 to 30 cm. above the pubis. They began to subside in size even from the second or third sitting, shrinking about 1 cm. a week, but menstruation usually was not arrested under two or three months. In 60 per cent. of the total cases only twelve or fourteen sittings were required, so that the course took only from ten to twelve weeks, and the women continued their usual life all the time, and there was no suffering of any kind. The fibromas subside much more rapidly than at the natural menopause, so that the treatment must act on the tumors directly, as well as indirectly through the ovaries.

The Fluorometer.—Guilleminot's fluorometer determines the dose of the roentgen rays by the power of the rays to render fluorescent a small luminous screen.

Roentgen Treatment of Bone, Joint and Gland Tuberculosis.—Cottenot has been able to compile a long list of local tuberculous lesions which have been benefited by roentgen

treatment. It is still a question whether tubercle bacilli are destroyed by the rays, but there is general agreement that the cells of the tubercles are destroyed by them while proliferation of connective tissue is promoted. He deplors that notwithstanding the fine results realized from irradiation of bone and joint tuberculous processes during the last ten years, this treatment has not yet won the place that its efficiency and harmlessness deserve. It would avert the necessity for surgical measures and prolonged courses of heliotherapy. The best results have been realized to date with tuberculous processes in the small bones, as they are more accessible to the rays. He has cured many cases of processes in long bones and joints by combining roentgen irradiation with immobilization after evacuating pus and sequesters. The hip joint is almost beyond the reach of the rays; only Schede has reported two successful cases of coxalgia. Iselin has reported more than 800 cases of cured tuberculous osteoarthritis.

Roentgenoscopy of Painful Points.—Jaulin advises the roentgenologist to pay special heed to the tender points, and to outline them with a metal ring, as an important aid in the differential diagnosis.

Functional Insufficiency of the Pylorus with Duodenal Ulcer.—Constantin found that the pylorus allowed the contrast suspension to pass at once into the duodenum in six cases of duodenal ulcer. This insufficiency may be spontaneously manifest or can be induced by pressing on the prepyloric region. It may be latent and transient, but it seems to accompany duodenal ulcer often enough to have differential importance. In two other dubious cases, this insufficiency was not evident.

Presse Médicale, Paris

*Internal Treatment of Psoriasis. R. Sabouraud.—p. 53.

*Ulcerating Mouth and Throat Lesions. David and Hecquet.—p. 54.
Angina Pectoris. R. Benon.—p. 56.

Internal Treatment of Psoriasis.—Sabouraud affirms that the treatment of psoriasis has entered on a new era of late with the discovery that certain measures which have nothing in common, except that they all give a kind of shake-up to the organism, are proving effectual in certain cases, although not in all. The list includes injection of mercurial salts, of antitoxic serums, and of emulsions of killed microbes from the patient's stools. There is hope that still more effectual means of inducing the shake-up or shock may yet be found. The field of experimentation seems immense and almost unlimited. Danysz' enterovaccine from the stools seems to be harmless, and great improvement under it seems to occur in more cases and to last longer than with any other measures yet known.

Ulcerative Lesions in the Mouth.—David and Hecquet write from Roumania to tell of their finding Vincent's fusiform bacilli in ulcerating lesions in the mouth and pharynx, which at first were ascribed to the prevalent scorbutus. In a recent twenty days, they encountered twelve cases of Vincent's angina. Glycerin solutions of arsenobenzol have proved useful.

*Abnormal Forms of Appendicitis. A. Possollo.—p. 707.
*Sugar Treatment of Pulmonary Tuberculosis. Ramiro Magalhães.—p. 736.

Abnormal Forms of Appendicitis.—Possollo reviews the unusual clinical picture that may be presented when the appendix is not in its normal place but is pushed to the left or is involved in a hernia or is adherent to pelvic organs, etc., or some infectious process elsewhere modifies the symptoms, or a tumor, constitutional disease, tuberculosis or actinomycosis may modify it, or the age may affect it, as when appendicitis develops in the infant or the aged. He remarks that while the diagnosis of appendicitis is not always easy under the most normal conditions, it is sometimes almost impossible under some of those just described. He has found the Abderhalden reaction a valuable aid in certain puzzling cases; in one, the presence in the blood of the special appendicular ferments gave the clue to the disease, confirmed by the operation. In another case the negative findings were confirmed by the operation which revealed right salpingitis. In a third, the positive findings conflicted with the presumptive diagnosis of colitis, but time proved the Abderhalden findings the correct ones. In a fourth case the findings were still positive two months after the appendix had been removed. Mariaute's experience has also confirmed that abnormal cases of appendicitis can be elucidated and confirmed by the Abderhalden reaction. In one case described in detail the young woman for two years had been having intense pain in the right iliac fossa at each menstrual period, but was free from pain during the intervals. It was so severe in the right hip and leg that she could not use them while it lasted. Possollo incriminated the appendix, and it was found pathologic, with a grape stone in it. In another case the septicemic appendicitis showed no local symptoms, no digestive disturbance, nor rigid abdominal wall. The only symptoms were those of acute nephritis, pain in the lumbar region and blood in the urine.

Sugar Treatment of Tuberculosis.—Ramiro Magalhães applied Lo Monaco's method of injections of sugar solution in forty-eight cases of pulmonary tuberculosis with negative results.

*Ichthyosis. Werneck Machado.—p. 385.

Epidemic Poliomyelitis in Uruguay. V. Escardo y Anaya.—p. 389.
Cont'n.

Ichthyosis.—Werneck Machado gives an illustrated description of three cases of ichthyosis in children now under treatment in his service. He knows of only five other cases in Brazil. Two of his own three cases are brother and sister, and others tell of cousins with the same trouble. In two of these eight Brazilian cases the infants were 2

and 4 months old, but one patient is a young man. The parents were cousins in one case, and inherited syphilis was evident in two others. In treatment, besides the general tonics and special measures, efforts to rouse the skin to better functioning are indicated, and among these he commends in particular jaborandi and its alkaloid, pilocarpin. Fox ascribes to thyroid treatment the recovery in his case. Polyglandular treatment might prove more effectual in other cases. Great improvement was realized under mercury and potassium iodid in one child with a syphilitic father. In addition to other external measures, steam baths and Russian baths have proved useful.

 *Urinary Calculi. C. Morales Macdo.—p. 342.
 *Pathogenesis of Delirium Cordis. M. Arias Schreiber.—p. 350.
 *Forensic Case of Oxalic Acid Poisoning. L. Avendaño and M. A. Velásquez.—p. 353.
 *Case of Hirschsprung's Disease. E. P. Manchego.—p. 359.

Bacillary Dysentery in Peru.—Although Escmel has made it his routine practice for fifteen years to examine the stools in cases of dysentery, he never found any bacilli that could be incriminated except in an epidemic of dysentery at Yura in 1917, and this did not spread beyond the limits of the town. The dysentery proved amenable to the treatment which has yielded such constantly good results in trichomonosis by his technic. His method has been described in these columns, May 17, 1919, p. 1501. It consists essentially in three enemas daily composed of 15 or 20 drops of oil of turpentine emulsified with the yolk of one egg and 60 gm. of distilled water, and from 5 to 20 drops, according to age, of laudanum. Each enema is retained as long as possible. An astringent, bismuth salicylate, and camphorated tincture of opium are given by the mouth, with hot applications to the abdomen every two hours. The prompt recovery under this combined treatment seems to indicate that these bacilli live in the rectum, as a rule. The liver returned to normal as the other symptoms subsided, which testifies that the liver complications are of toxic origin, the hemorrhoidal veins providing a ready means of access for the toxins from the rectum. Escmel was recently awarded a prize by the Académie de médecine at Paris for his notable contributions to the knowledge and treatment of tropical diseases.

Operative Indications for Calculi in Kidneys or Ureters.—Morales reviews nine different conditions that may be induced by renal lithiasis, and the indications with each. As general contraindications he cites syphilis and tuberculosis, which should be given treatment before operating for stone, outside of emergency cases. The operation also should be postponed with gonorrheal arthritis, or very violent gonococcus infection of any kind. The temperature and lack of any recent great loss in weight are also instructive. The heart, blood pressure, blood count, etc., should never be neglected, and with very nervous patients, it may be advisable to delay the operation until a course of psychotherapy has been given.

Delirium Cordis.—Arias presents evidence to show that fibrillation may be of nervous origin in some cases. This explains the cases in which the general condition keeps good, notwithstanding the permanently irregular pulse.

Megacolon.—Manchego's patient was a man of 38 and the Hirschsprung disease was not recognized until the abdomen had been opened by an exploratory laparotomy.

 *Liver Tumor in Infant. Casaubon and Bacigalupo.—p. 183. Cont'n.
 *Psychology of Aphasia. Enrique Moucher.—p. 187.
 *Wiring of Aneurysm. Nicolas Tagliavacche.—p. 189.

Fracture of the Tibia.—Celesia is delighted with the results obtained in twenty cases with a light plaster cast applied to allow free use of the knee and ankle after fracture of the tibia. The patient could walk about while the fractured bones were healing under the immobilization, the plaster collar above and below fitting against the tuberosities of the tibia and the malleoli. The patients are walking by the second or third day, and the muscles keep well nourished and strong.

Liver Tumors in Infants.—Casaubon and Bacigalupo report a liver tumor in a 10 months babe. Several photomicrographs are given, and 33 cases of neoplasms in the liver in children are tabulated as compiled from the literature, and 11 cases of metastatic liver cancer. The primary tumor was in the right kidney in 4; in the left in 5, and in the pancreas in 2. In one infant of 2 months a sarcoma had developed in both liver and suprarenal at the same time. These cases supplement the 28 compiled by Steffen.

The Psychology of Aphasia.—Moucher describes a case of aphasia in a man of 63 and lists sixty-six titles on the psychology of aphasia.

Wiring an Aneurysm.—Tagliavacche gives an illustrated description of an aneurysm of the descending aorta in which marked improvement followed wiring, introducing 21 meters of copper wire. The patient is a man of 64 in such a grave general condition that long survival is not to be expected.

 Influenza Bacillus Meningitis in Infant. J. P. Garrahan and C. Gourdy.—p. 220.
 Arrhythmias. P. M. Barlaro.—p. 221. Continuation.

Chronic Mediastinitis from Tardy Inherited Syphilis.—Castex and Beretervide say that chronic mediastinitis of syphilitic origin in children has been well studied and also from acquired syphilis in adults, but they do not know of any case like the one they describe in a man of 28 in which there were other manifestations of inherited syphilis, and the mediastinitis was a recent tardy development. The compression of the vena cava dominated the clinical picture. The slow but progressive improvement under specific treatment showed that the trouble was from gummas rather than from irreparable sclerosis.

Electric Device for Electrodiagnosis.—Tedeschi gives an illustrated description of his apparatus which, he says, avoids the errors of other chronaximeters and similar apparatus. The current passes merely during the impact of two elastic balls.

- *Ankylosis of the Knee. J. M. Jorge.—p. 539.
 *Poisonous Anise. J. V. Negrete and C. F. Velarde.—p. 554.
 *Percutaneous Tuberculin Treatment. S. de Madrid.—p. 565.
 *Cyst in Infant's Spleen. J. Bacigalupo and A. Grosso.—p. 576.
 Resolutions Adopted by Argentine Tuberculosis Congress.—p. 578.
 *Eugenics. L. Mathé.—p. 581.

Ankylosis of the Knee.—Jorge gives roentgenograms of ten cases of ankylosis calling for surgical treatment. He warns that it must not be forgotten that the tissues around the joint are less resistant than normal, and cannot stand much pressure. He warns further that typical resection of a joint should not be done on a child either for arthritis or ankylosis. One of the illustrations shows the irreparable damage done by resecting the knee for a tuberculous process at the age of 14. Jorge reiterates that the epiphyseal cartilage should always be held absolutely sacred and left unmolested.

Toxicity of Japanese Star Anise.—Negrete and Velarde have been studying samples of *Illicium religiosum* which had caused sickness in a number of children. It is evidently a poison for the central nervous system, inducing in all the

laboratory animals tested periodical or subcontinuous convulsions and paresis. The symptoms are so typical that it might prove useful as a drug for biologic tests.

Tuberculin Treatment by the Percutaneous Route.—De Madrid has given this treatment in hundreds of cases and here defines its indications and contraindications, and extols its importance as an adjuvant to other measures.

Cyst in Spleen.—The cyst was found in an infant cadaver, the child having died from bronchopneumonia. No symptoms had called attention to the spleen.

Eugenics.—Mathé defines eugenics as applied physiology and biology extended to include collective life. Physicians must take the lead in the new science, he declares, but they must secure the cooperation of sociologists and legislators. Eugenics is closely connected with the fight against alcohol and overcrowding, tuberculosis, and syphilis.

Proposed Reforms in Medical Course. O. Lubarsch.—p. 1044. Conc'n.

Exceptionally Long Roentgen-Ray Treatment Finally Successful in Case of Polycythemia.—Forschbach reports a case of erythremia that required an unusually long period of roentgenotherapy before the cure was finally realized. The patient, a man of 61, was admitted to the hospital in 1912, complaining of pains in the epigastrium, dizziness and rush of blood to the head. The findings in May, 1912, were: cyanotic appearance of the face; mild peripheral arteriosclerosis; enlargement of the spleen and liver; blood pressure, 165; erythrocytes, 6,000,000. The diagnosis was the hypertonic form of erythrocythaemia rubra. By July, 1916, his condition had grown much worse. At times, on account of dizziness, the patient could not walk alone. The erythrocyte count now varied from 7,000,000 to 12,500,000; hemoglobin was from 100 to 150 per cent.; the white cell count was from 10,700 to 13,600; the urine contained, from time to time, albumin and casts. Venesection brought no relief. July 22, 1916, deep roentgen irradiation of the long bones was begun. The irradiation period usually covered eight days, and was followed by a week's rest, at first; later, the intervals depended on the appearance of the blood picture. The first two periods of treatment had no effect whatever on the blood picture, so the treatments were discontinued, although the patient himself protested that irradiation had brought subjective relief. In the meantime Forschbach's attention was called to the case of Tancre, in which a reduction of the red corpuscles from 14,200,000 to 6,600,000, and of the hemoglobin from 175 to 163 per cent., was brought about. Forschbach was thus encouraged, after the lapse of a year, to recommence treatment in September, 1917. The long bones were treated in the same manner as before, but with longer pauses. Not until after the eighth period of treatment, given from April 9 to May 11, 1918, did the red cell count begin to fall rapidly. By Sept. 13, 1918, it had fallen to 3,300,000 and the hemoglobin to 62 per cent. The treatments were discontinued and by April 23, 1919, the red

cell count was 4,796,000 and the hemoglobin 90 per cent. There was also very great improvement in the subjective symptoms. For duration of treatment Forschbach thinks that his case surpasses all reported thus far. He warns that an exceedingly careful control of the red and white cell count must go hand in hand with the use of roentgenotherapy in erythremia in order to avoid serious leukopenia. Pre-monitory lowering of the white cell count is an indication to lengthen the intervals of rest between the exposures to the rays.

Staining of Guarnieri's Bodies.—Hesse has been trying to improve on previous methods of staining Guarnieri's bodies (vaccine bodies arising in the corneal epithelium of rabbits inoculated with vaccine lymph). He sought a quick method by which only the Guarnieri bodies would be stained, the cell nuclei, leukocytes and the products of cell degeneration remaining unstained. In preparing his stain he used 10 c.c. of a saturated alcoholic solution of cresyl-fast violet (Grübler) added to 90 c.c. of a 5 per cent. phenol solution. The stain is thoroughly mixed and filtered, and can then be used at once. After the slides have been washed with xylene to remove the paraffin, and the xylene has been removed by means of absolute alcohol, the sections are stained for from fifteen to twenty minutes with the cresyl-fast violet; and, without being rinsed in water, a fresh 2.5 per cent. aqueous solution of ammonium ferric sulphate is used as a mordant. The slides are now rinsed in distilled water and are put for differentiation in a 60 per cent. aqueous solution of acetone. The differentiation requires from twenty to thirty minutes, and, until one is thoroughly experienced, should be observed under the microscope. Thus the moment when the cell nuclei and leukocytes have given off the last bit of stain may be ascertained; while, it will be noted, Guarnieri's bodies are distinctly differentiated by a rather dark violet hue. Hesse's investigations with the above described stain lead him to the conclusion (which he considers important) that Guarnieri's bodies are not derived from the nuclei of leukocytes or epithelial cells. The fact that Guarnieri's bodies have entirely different staining characteristics, together with their peculiar structure, indicates, Hesse thinks, their specific origin.

Kidney Function in Diabetic and Postdiabetic Conditions.—Weil distinguishes three forms under which albuminuria may be combined with diabetes: (1) A harmless albuminuria, associated with glycosuria and receding with the disappearance of the sugar, or with the decrease of the high sugar content (saccharogenic albuminuria so called); (2) albuminuria caused by a complicating arteriosclerosis or arteriosclerosis (diabetic nephrosclerosis), and (3) albuminuria produced by genuine nephritic processes (diabetic nephritis or nephrosis). He states that recent progress in the examination of diabetics has made possible a closer differentiation between benign and malignant forms of nephrosclerosis. He thinks, therefore, that in diabetic nephrosclerosis kidney function tests should be made more frequently than has been done in the past. Often the functional activity will be found to be the same as in simple nephrosclerosis, so that, for the time being at least, the prognosis is more favorable than it would otherwise appear. In other words, from the diagnostic and prognostic standpoint, diabetic nephrosclerosis may be viewed in much the same light as nondiabetic nephrosclerosis.

Myoma of the Pleura.—Kornitzer was unable to find in the literature any descriptions of pleural myomas, as in a case reported. His patient, a man, aged 40, was admitted to the hospital, July 27, 1917. Examination revealed dullness over the right thorax, and respiratory and vocal fremitus could not be elicited. Subfebrile temperatures were noted. Puncture revealed hemorrhagic fluid. The diagnosis was hemorrhagic pleuritis. The disease took a rapid course. August 13, pleural puncture was done and one-half liter hemorrhagic fluid was removed. August 16, the patient died. Necropsy revealed a poorly nourished but strongly built man. On loosening adhesions of the left lung, a round, apple-sized tumor of tough, elastic consistency was found on the posterior surface of the inferior lobe. The tumor,

which Kornitzer calls a fibroleiomyoma, was enclosed in a hard capsule. There were no very firm adhesions between the tumor and the surrounding tissues, but it was attached to the lung by a fibrous strand. This fibrous strand and the free surface of the tumor were covered with pleural endothelium, which was connected with the endothelium enveloping the lung. At the cut surface the tissue was grayish yellow. In the center of the tumor were cavities as large as a cherry, though not sharply outlined. In the right pleura an endothelioma was found, from which, besides numerous other metastases, one of microscopic size had developed in the above described fibromyoma. Kornitzer thought, at first, that the subpleural tissue might perhaps be assumed to be the point of origin of the fibromyoma, but he found in the textbooks on comparative anatomy and embryology no reference to smooth muscle fibers occurring in the pleural tissue. He thinks, therefore, that we must assume that muscle cells, cast off from the walls of blood vessels, constituted the tissue from which the tumor took its origin.

- So-Called Ulcer Carriers. G. B. Gruber.—p. 1294.
- *Abuse of Phenolphthalein. L. Schliep.—p. 1294.

The Spring Peak of Tetany.—Moro's curves confirm the seasonal prevalence of tetany, its gradual increase during the fall and winter months, to its apex about March, when it falls sharply, and then drops off more gradually until midsummer. In adults with a tendency to tetany, as spring approaches, the skin of the hands often feels dead or leathery. Moro connects these facts with the markedly increased irritability of the vasomotor nerves and the vegetative nerve system, and with the increased activity of internal secretions that regularly occur in spring. He adds, "It has been said, 'Night is the time of the unstriated muscle,' and the awakening of the instincts in the animal kingdom shows that it can be said likewise, 'Spring is the time of the internal secretions.'"

Treatment of Surgical Tuberculosis.—The conditions of the war period in Germany, Kisch says, have caused not only a deplorable increase of tuberculosis, but the disease appears also in more serious forms. In surgical tuberculosis, the patients usually have, either simultaneously or consecutively, several foci of infection, often as high as seven or more, and they are characterized by profuse suppuration. The large number and wide extent of the foci, together with the weakened general condition of the patients, and their vast numbers, make it impossible to apply operative measures in all the cases of tuberculosis of the bones, joints, and glands. Kisch employs heliotherapy (natural and artificial) aided by passive hyperemia, and administers sodium iodid. As regards tuberculin treatment, he thinks it will, when used alone, effect a cure only in selected cases. He himself has effected cures by its exclusive use in spina ventosa and scrofuloderma in children, and beginning soft swellings of the lymphatic glands have disappeared. Heliotherapy is applicable to all cases. Kisch states that in the sanatorium associated with the Berlin university surgical clinic, in the majority of cases, immediately after a tuberculous focus has cleared up, or even before, tuberculin treatment is instituted to prevent new foci. Occasionally, because of unfavorable reactions, further tuberculin treatment is contraindicated. Under heliotherapy as described by Kisch, patients with unusually severe tuberculosis of the joints have been cured, and a normal, or at least adequate, function of the joints has been restored. A number of patients over 50 and even 60 years old, with severe tuberculosis of the spine, have been cured. Patients with severe tuberculosis should always be treated in sanatoriums far removed

from large cities, where they can get the maximal benefit from sunlight and fresh air. Mild cases may be treated in sanatoriums located at the edge of large cities, so that patients, if necessary for financial reasons, may continue to follow their calling.

Urology and the General Practitioner.—This six-page article is made up of material used by Schlagintweit in a graduate course of lectures. He regrets that most general practitioners have never taken a thorough course in urology. By the average practitioner the kidneys are looked on and studied as one connected organ, whereas the urologist carefully considers the function of each kidney separately. He says that 33 per cent. of all chronic, suppurative processes of the urinary apparatus are of a tuberculous nature. The presence of white corpuscles in the urine is the most significant urinary symptom. Pollakiuria in the daytime, but not at night, can be only of nervous origin, especially if micturition is not painful or difficult, for any inflammatory irritation or congestion of the bladder or the region of the vesical sphincter will awaken the patient at night by the desire to urinate. Under such conditions, when the bladder fills to a certain degree, it manifests itself as regularly as an alarm clock. In the case of an old man, frequent desire to urinate at night, provided he has to strain and wait for the flow to begin, or has to walk around a while first, may be taken as a sign of hypertrophy of the prostate. The cardinal urologic symptoms which Schlagintweit regards as indicating the urgency of a thorough instrumental diagnosis and therapeutics, possibly necessitating local or general anesthesia are: (1) acute retention of urine; (2) unendurable pain, especially colicky pain; (3) fever; (4) total anuria; (5) chronic uremia; (6) rapid emaciation, and (7) severe hemorrhage. Aside from the foregoing indications, all urologic diseases may be profitably treated by rest in bed, application of heat and the administration of mild narcotics, for two or three weeks, until the true condition of affairs can be cleared up. Urologic diseases, especially those of the lower urinary passages, that do not clear up promptly following rest in bed, are usually due either to some mechanical cause or to some pathologic condition of the upper urinary passages; for example, a cystitis arising from a pyelitis or prostatitis. We must never assume that a pyelitis that has existed for years is incurable without considering that the condition may be unilateral, and that it may be cured by unilateral nephrectomy.

Value of Fluid Human Fat (Humanol) in Surgery.—This article is a preliminary report of Loeffler's experimental use of humanol (fluid human fat) in surgery. He has been using humanol for three years and it has given excellent results. Humanol is obtained from the fatty tissue secured in connection with operations (abdominal fat, lipomas, etc.). All connective tissue is removed, and the fat is then heated for three hours over a water bath and filtered. Only the fat of healthy persons is used. Good results were secured by using humanol for the isolation of tendons and nerves from adhesions, and to prevent the formation of new adhesions. After the tendon or nerve has been removed from surrounding adhesions and all hemorrhage has been stopped, the wound is closed, leaving a pinhead opening just large enough to admit the tip of the syringe. The suture is drawn tighter, the humanol is injected, and the suture is then tied. Light effluage spreads the humanol around. The wound heals well, and the cicatrix is soft and elastic. In numerous tendon transplantations on the foot, in infantile paralysis, humanol was used, and there were no disturbances caused by adhesions. In hand and finger injuries humanol found its widest application. Loeffler has not been able to discover that humanol softens scars as claimed by Wederhake. In joint injuries (arthritis deformans, arthrogenous contractures) it was found useful. Iodoform glycerin had come to be regarded as most valuable in treating the rapidly increasing number of cases of tuberculosis of the bones and joints. But glycerin became scarce and was of poor quality. Then again, a high fever was often caused by the injection of small quantities of iodoform glycerin. Accordingly, Loeffler used 5 or 10 per cent. "iodoform humanol," injections of

which gave exceptionally good results. Iodoform glycerin has therefore been discarded. As humanol is absorbed within from five to seven days after subcutaneous injection, Loeffler cannot recommend its use for plastic purposes. If mixed with animal and vegetable fats (e. g. tallow), the humanol is absorbed, while the other ingredients are left as a foreign body.

Indications for Splenectomy.—Kleeblatt states that the spleen is being removed nowadays in all sorts of cases, without very clear indications therefor. However, after other forms of treatment have failed, tumors of the spleen, associated with kala-azar and malaria may justly be removed for mechanical reasons; for example, on account of rupture or too great size. Now that we assume that leukemia is a systemic disease affecting the lymphatic glands and the bone marrow, and that the enlargement of the spleen is only an accompanying phenomenon, the failures following extirpation of the spleen should no longer cause surprise. Removal of the spleen for polycythemia is not indicated, for the reason, he says, that the disease, though it has various etiologic factors, has nothing to do with the spleen. Küttner and others have reported cases of polycythemia arising after extirpation of the spleen. In isolated tuberculosis of the spleen, removal of this organ rests on a good basis. It is also indicated in all diseases attended with severe hemolytic processes; for example, hemolytic icterus, hypertrophic cirrhosis of the liver and atrophic cirrhosis (Banti's disease) in the first and second stages, but only as a last resort in the third stage. In pernicious anemia the good effects are transitory. Splenectomy is contraindicated in thrombosis of the portal vein and all disease processes caused by primary portal stasis. The urobilin excretion as a measure of the hemolytic processes in the body (Eppinger), Kleeblatt thinks, may eventually make clear the indications for extirpation of the spleen.

Gangrene of Bladder Following Vaginal Carcinoma Operation.—A long convalescence followed an uneventful operation for carcinoma of the portio vaginalis performed by Hisgen on a 28-year-old nullipara. After the operation the patient presented a septic appearance. The urine contained more and more blood, and by the seventh day had a strong odor. Bladder lavage was done and hexamethylenamin was administered. On the seventeenth day the lower end of the abdominal incision began to swell, and on the twenty-fifth day it broke open, and an incredible quantity of foul-smelling fluid was evacuated. A piece of necrotic tissue almost the size of a man's hand appeared in the wound and was removed. The palpating finger was able to touch through the fistula a catheter introduced through the urethra. It was thus evident that there was an extensive defect in the bladder wall. A retention catheter was inserted in the urethra and lavage several times daily was done. The temperature gradually became normal, the urine clearer, and the odor less noticeable. In three weeks the fistula in the abdominal wall had closed and the catheter was removed. Two months after the operation the temperature was normal. The patient was free from subjective symptoms, but was much emaciated. The cystoscopic examination, just before the patient was dismissed, revealed that the region of the trigonum was scarcely changed; both ureters were functioning normally. At the base of the bladder, next to the posterior wall, there was whitish, shiny tissue (doubtless scar tissue). In three months the patient had completely recovered. The primary cause of the condition was doubtless deficiency of the blood supply owing to the bladder wall having been detached to such an extent. Secondly, an infection from the wound cavity in the pelvis destroyed completely the badly damaged portion of the bladder wall. Whether adhesions had roofed the space could not be definitely ascertained, but, in any event, the patient can now retain the same amount of urine as before the operation.

Treatment of Old Ulcerating Wounds.—Pürckhauer reports his success in using Drehmann's method of treating old ulcerating wounds, and regrets that the method is not better known, as the prompt results secured make it worthy of the widest recognition. The physiologic principle on which the

method is based is the securing of a better blood supply by removing obstructing factors. The wound is scraped with a sharp curet, and then a circular incision is made in the surrounding healthy tissues down to the fascia, and even through the fascia, in case there are strongly supporting bones, as, for example, in the front of the leg. The edges of the wound are approximated by means of adhesive strips. After about five days the strips are removed, showing surprisingly good results. The base of the wound, which had presented a dead appearance, is covered with fresh, lively granulations, and the surface of the wound is considerably smaller. Fresh adhesive strips are applied and in a short time the wound is healed. Rest in bed must be strictly observed. Pürckhauer has thus succeeded in causing wounds to heal that had defied all other treatment for months and even years. Some of the ulcerating surfaces had been as large as a saucer.

The Abuse of Phenolphthalein.—In view of the fact that Fuld's warning uttered in 1909 does not seem to be heeded, Schliep calls renewed attention to the fact that phenolphthalein even in small doses of 0.1 gm. [the U. S. P. average adult dose is 0.15 gm.] may cause serious hemorrhagic nephritis attended by severe anemia. He regrets especially that phenolphthalein is used as an ingredient of biscuits, cakes, chocolate confections, bonbons, drops, etc., as these are given to children in indiscriminate quantities without a physician's prescription. Schliep has compiled a list of seventy-two proprietaries containing phenolphthalein, which he reports in full, and cites a few cases of severe phenolphthalein poisoning in Germany. One man of 59 had transient heart failure and nephritis after he had taken only 0.6 gm. in the course of twenty-four hours. In two other cases there were hemorrhagic nephritis and jaundice with serious collapse.

*Intraspinal Medication. G. Neumann.—p. 401. Conc'n.

*Thermal Baths in Cardiovascular Disease. Grunow.—p. 406.

*Puncture Treatment of Anasarca. R. von den Velden.—p. 417.

*The Capacity for Synthesis of the Human and Animal Cell. Grumme.—p. 421.

Intraspinal Treatment Exclusive of Serotherapy.—The first instalment of Neuman's article was briefly summarized on page 143. The final conclusions of the article state that the outcome of intraspinal treatment of tuberculous meningitis with tuberculin and of tetanus with silver preparations is dubious, and that intraspinal treatment with magnesium sulphate is fraught with danger and can be replaced by other methods. Intraspinal administration of drugs seems to have benefited in treating meningitis with sodium chlorid solution, Ringer's fluid, optochin, and silver preparations. But the number of cases to date is too small for a conclusive judgment. A decision is most difficult in respect to the effects of intraspinal administration of arsphenamin. It has proved unquestionably successful in certain cases of neurosyphilis, but this generally responds well to treatment by the vein. The clinical symptoms in tabes and progressive paralysis do not always keep pace with the serologic improvement. To date there is no evidence to prove that tabes and paralysis can actually be arrested by intralumbar treatment, as some maintain. She concludes the article with the remark that the dangers of intraspinal treatment seem great, and out of all proportion to the benefit therefrom. It should be applied only after failure of other measures. A bibliography giving the titles of sixty-six articles is appended, including three from THE JOURNAL.

Thermal Baths with Cardiovascular Disease.—Grunow refers to thermal mildly saline, noncarbonated waters, supposed to be strongly radioactive, and discusses the indications and contraindications. An especially favorable influence may be expected with arteriosclerosis and intermittent limping; aortic defects; syphilitic vascular lesions; gout and obesity, provided the myocardium with the latter is functionally capable; and neuroses of the heart and vascular system. The waters soothe the tendency to spasm and dilate

contracted vessels, but special care is necessary when there is a neurotic tendency. The finest results have been realized in Raynaud's disease and similar conditions.

Puncture in Treatment of Edema.—Von den Velden comments on the dread which general practitioners so often display in respect to tapping anasarca. He gives the tracings from two of twenty-three cases in which the benefits from puncture were particularly striking. In one, the weight dropped 16 kg. in three days after puncture of the skin on both legs; in the other case 13 liters of edema fluid drained away in one day, to a total of 25 liters by the sixth day. The puncture is done with a fine trocar, 0.5 to 1.5 cm. deep, in a series of from five to fifteen rows of puncture holes, 1 or 2 cm. apart, on the foot or leg where the edema is the most pronounced. From fifty to eighty puncture holes were thus made on each leg, as a rule, and the results far surpassed those with incisions and cannulas. Small incisions heal up too quickly; large ones heal badly. The patient is prepared three or four hours beforehand by shaving the legs and wrapping them in cloths moistened with alcohol or mercuric chlorid solution, as he sits in an easy chair, the feet on a soft stool. The punctures take only a few minutes, only two minutes with practice, and the legs are then wrapped anew and the patient stays in the chair for at least a day. The dressings are changed twice in twenty-four hours, and no disinfectants are used. A little morphin beforehand may be advisable.

Assimilation of Inorganic Mineral Salts.—Grumme presents arguments to prove that inorganic iron cannot be assimilated, as also all mineral salts not combined with albumin, and he refuses to accept the statements in the literature to the contrary. He declares that the experiments and experiences on record do not justify the conclusions that have been drawn from them. Inorganic iron, he insists, has merely a stimulating action. The only iron or calcium that is assimilated is that in the food, as it is combined with groups of albumin atoms. Animals perish when they are deprived of organic iron, even although they may be getting large amounts of inorganic iron. It may be possible, he suggests, to add to iron-poor food some artificially prepared combination of albumin and iron which might be readily assimilated and bring the food up to the required level of organic iron.

Nov. 15, 1919, 2, No. 20

*Examination and Diplomas. G. van Rijnberk.—p. 1513.

*Whooping Cough. B. H. Sajet and J. van Gelderen.—p. 1525.

Hospitals and Sickness Insurance. C. W. Vrendenberg.—p. 1546.

Examinations.—Van Rijnberk discusses what examinations are good for and what they should be. A passage from a recent work by B. Fischer is quoted which states that in Germany the incompetents are not weeded out by the examinations, "so that there is no one so feeble-minded or incompetent (aside from the insane requiring internment) that cannot in time and finally pass the examination for the medical degree."

Whooping Cough and Its Prevention.—Sajet and van Gelderen analyze the statistics in regard to whooping cough at Amsterdam since 1890. Among the curious facts thus brought out is the increase in the mortality from whooping cough from 3.81 to 5.99 per cent. of the general mortality in 1890-1899 and 1907-1916, respectively. Another fact is the higher mortality in the northern and western parts of the country, and in the bleaker months. Children of the poorer classes contract whooping cough from their mates while quite young. Only 10 per cent. developed it during the school years, while the children of the well-to-do escaped it young, 37 per cent. acquiring it in school. As whooping cough grows less and less dangerous for a child after the age of 5, this testifies to the graver danger from whooping cough for the children of the masses. The mortality under 1 year was 42.3 per cent.; from 1 to 5, 55.9 per cent., and above the fifth year only 1.8 per cent. It is mentioned further that the mortality from whooping cough was three and a half times smaller in Jewish families than in others. In prophylaxis

they urge the special importance of protecting the younger children against infection with whooping cough. Every child admitted to an institution for quite young children should be regarded as suspected of various acute infectious diseases until time proves the contrary. They advocate that compulsory notification should be enforced, and a service for combating acute infectious diseases should be organized, as also ample hospital facilities for whooping cough children.

*Muscular and Reflex Segmentation of Abdominal Wall. G. Söderbergh.—p. 647.

*Changes in the Blood After Experimental Feeding with Spleen Tissue. A. Brinchmann.—p. 689.

Neurology of Abdominal Wall.—Söderbergh's article is in French. He reviews his previous researches and adds the results of new on the innervation of the abdominal reflexes, according to the segment of the spinal cord and roots involved. Eleven clinical cases of spinal paresis or meningitis are analyzed. It must be borne in mind, he says, that the motor and reflex symptoms are more objective than the sensory symptoms. Also that the extramedullary tumors are almost all located in the dorsal region of the cord. The extent of the area of rigidity is instructive.

The Blood on a Spleen Tissue Diet.—Brinchmann fed guinea-pigs and rabbits on fresh beef spleen, and devotes nearly a hundred pages to minute analysis of the changes in the blood on this diet. Within two hours after the meal the number of both red and white corpuscles is much reduced, the reds dropping off by 11 per cent. and the whites by 21 per cent. on an average, the lymphocytes by 37 per cent. The blood usually had returned to normal by the end of two hours.

*Operative Treatment of Embolism. H. Sundberg.—p. 1.

*Some Ancient Remedies. H. Kjerrulf.—p. 12.

Operative Removal of Embolus.—Sundberg reports another successful case to add to the 6 on record in which an embolus was removed from an artery (exclusive of the pulmonary artery), with a permanent cure. These 6 are the only permanent cures from arteriotomy in the total of 20 cases he has compiled, and in 4 of this group of 6 the operation had been done by a Swedish surgeon. In his own case the patient was a man of 63 with myocarditis and extensive arteriosclerosis, and the embolus was drawn out, and the artery sutured afterward with button sutures, the suture taken only through the outer and middle coats, using a fine curved needle and extremely fine silk lubricated with petrolatum. There was no bleeding, and the man has had no further disturbances from it since. Sundberg ascribes the lack of thrombosis later to the exact coaptation of the walls of the artery and the fact that no sutures entered the intima. The patient was the oldest one on whom such an operation has been performed, and the heart disease and arteriosclerosis and the long interval render the success all the more striking. In Proust's case the interval was fourteen hours and the thrombus was 12 cm. long; in Lundmark's case, ten hours, and 3 cm. long, and in the present case, twelve hours and the thrombus was 86 cm. long. The operation was done under local anesthesia and 0.015 gm. morphin. The longitudinal incision was 2 cm. long, just at the point of the bifurcation of the common femoral artery. The upper end of the embolus was drawn out and the spurting blood was arrested by clamping above, and clamping the deep femoral. The continuation of the thrombus in the superficial femoral was then seized with forceps and gently pulled out in one piece. Convalescence was retarded by a slight thrombophlebitis, but since then there have been no disturbances in the leg.

Ancient Remedies.—Kjerrulf gives a historical sketch of the aqua magnanimitatis of the seventeenth century, and of the use of formic acid as a drug, which was of still older origin.

GENERAL PROGNOSIS OF SYPHILIS IN THE LIGHT OF RECENT PROGRESS

SIGMUND POLLITZER, M.D.

NEW YORK

The additions to our knowledge of syphilis during the last two decades are: (1) the discovery of the spirochete; (2) the Wassermann test, and (3) the new organic arsenic compounds. To these achievements of primary importance may be added the use of the dark-field microscope and the employment of spinal puncture for diagnostic and therapeutic purposes.

DISCOVERY OF THE SPIROCHETE

The discovery of the spirochete is one of those fundamental additions to our knowledge, the ultimate effect of which it is impossible to gage. The whole field of experimental syphilis has been placed on a scientific basis, and progress is as inevitable as it was in other fields after the discovery of the germs of diphtheria, tetanus, etc. A vista of unlimited possibilities has been opened.

In the meantime this discovery has added a factor that has enormously improved the general prognosis of syphilis. It may be stated that there is no factor in the prognosis of syphilis that is comparable in importance with early and energetic treatment. The syphilis that has been generalized in the system, that has infected every organ and tissue, that, in the course of years, has induced sclerotic changes in important structures, presents an entirely different prospect of cure from the disease in its incipience. The treatment of syphilis by the vigorous exhibition of arsphenamin in its primary stage, while the disease is still largely a local infection and before the organisms have acted long enough on the tissues even to provoke the development of a positive Wassermann reaction, results in the immediate cure of the disease in practically every case. It is in its primary stage that the prognosis of a properly treated case of syphilis is at its very best. On this point there is universal agreement among syphilographers.

Twenty years ago this golden opportunity for the cure of the disease, even if we had then possessed the potent remedies now at our command, would have been allowed to pass. Twenty years ago it was the accepted practice to await the development of secondary lesions before instituting treatment. This practice was entirely justified in the existing state of knowledge. It was, as it is today, an admitted fact that the diagnosis of syphilis based on the clinical aspects of the initial lesion cannot be made with absolute certainty. On the one hand, the supposed chancre might not be syphilitic

and the patient therefore was subjected unnecessarily to the anguish and the hardship of a prolonged course of treatment; or, on the other hand, the institution of treatment in the primary stage, by suppressing the secondary manifestations, would in the majority of cases result in a doubt of the diagnosis on the part of the patient with consequent neglect to pursue the treatment to its end.

It is today a common experience for syphilologists to hear from a tabetic or an old cardiac syphilitic the story of a slight sore, its cauterization by the physician, the taking of some pills for a few weeks, and then nothing more in the way of treatment or of symptoms till the grave and possibly hopeless lesions of the late syphilitic made themselves manifest. It was, therefore, correct practice twenty years ago to await the development of secondary lesions, not only for the purpose of establishing the diagnosis on a firm basis, but also to convince the patient of the correctness of the diagnosis and thereby insure a greater fidelity to treatment. Waiting until the appearance of secondary lesions, however, meant waiting until there was a wide invasion of the system, waiting until a profound spirochetal septicemia was established. In the case of any other local infection, no one would think of postponing for a single moment the steps necessary to prevent systemic infection. Today, through our knowledge of the spirochete, with the aid of the dark-field microscope, we are able in a few minutes to make a positive diagnosis of syphilis in every case of untreated chancre and to take the necessary measures to cut short the further systemic infection.

The prognosis of syphilis has been immeasurably improved, in this respect alone, by the discovery of the spirochete.

At the other end of the scale of syphilitic lesions, Noguchi's discovery of the spirochete in the tissues of the central nervous system has definitely placed tabes and paresis—the affections formerly spoken of as parasyphilitic—in the group of syphilitic affections, bringing to an end the fifty years' controversy as to their nature. The new studies of the spinal fluid have brought out the fact that the foundation for these late lesions of the central nervous system is laid in the early stage of the disease, probably at the time of the first great generalization of the spirochetes; more than half the cases of syphilis show evidence of disturbance in the spinal fluid at this early period. On the other hand, it is a common observation that cases of tabes and paresis give a history of little or no treatment in the early days of their disease, and though there are exceptional cases that seem to have been well treated by the former methods, early neglect is the rule. The time to cure paresis and tabes is the time at which the

central nervous system is first invaded and before the anatomic lesions that follow many years later have developed. I venture to predict that with the diffusion of the knowledge of the supreme importance of early energetic treatment by the new remedies, the incidence of these terrible and generally hopeless effects of syphilis will greatly diminish, and the general prognosis of syphilis be proportionately improved.

THE WASSERMANN TEST

The second great achievement of recent years is the application of the Bordet-Gengou method of complement fixation to syphilis—the Wassermann test.

In all the fluctuations of opinion as to the significance and value of this test one fact has remained clear, namely, that a strongly positive Wassermann reaction is found practically only in syphilis, and that a strongly positive Wassermann reaction means syphilis.¹ This test has aided in the proof of the syphilitic nature of the late lesions of the central nervous system, of the sclerotic changes of the cardiac valves and of aortic aneurysm; it has abolished Colles' and Profeta's laws by showing that in these cases both mother and child are protected against infection because they are already syphilitic. It has awakened the profession and the public to the unsuspected extent of the prevalence of syphilis in every community in which a systematic investigation has been made, and by increasing our knowledge of the extent and gravity of the disease has served as the great stimulus to the administration of proper treatment and to this extent has benefited the prognosis of the disease in the individual. Never in the history of syphilis has there been so extensive a knowledge of its nature and so general an effort to curb its spread by education and other prophylactic measures along the lines of "social hygiene."

Furthermore, the Wassermann reaction is used as an index of the efficacy of treatment and thus as a prognostic sign. On the theory that the Wassermann reaction is due to the presence of certain bodies in the blood that are produced as the effect of an interaction of the spirochetes and the tissues, it is an obvious deduction that the disappearance of the Wassermann bodies from the blood indicates the disappearance of the spirochetes. Unfortunately, this deduction goes too far; the disappearance of the Wassermann bodies from the blood of the syphilitic, the occurrence of a negative Wassermann reaction, indicates only the cessation of the interaction of tissues and spirochetes and not necessarily the eradication of the spirochetes. It seems that a negative Wassermann reaction in a syphilitic means only that there are no foci of spirochetes in the patient sufficiently active to bring about the formation of an appreciable quantity of Wassermann bodies in the blood; but it affords no proof of the eradication of the spirochetes. We know that the late syphilitic with a gumma in the skin, or with obvious symptoms of syphilis of the central nervous system, frequently presents a negative Wassermann reaction. We know, furthermore, that vigorous treatment in the secondary or the later stages commonly results in a negative Wassermann reaction which subsequently may become positive. As an index of the complete spirochetal disinfection of the patient, a negative Wassermann test at a given moment is relatively useless. On the contrary, however, as an index of failure to eradicate the

spirochetes, a positive Wassermann reaction in the syphilitic under treatment has the greatest value and demands the continuance of treatment.

This brings us to the question of the significance of a positive Wassermann reaction in the old asymptomatic syphilitic. I have in mind two classes of cases:

First, the syphilitic who has been well treated for several years, whose spinal fluid is negative, who presents no physical evidence of his disease, but whose blood serum persistently shows a strongly positive Wassermann reaction, which energetic courses of treatment have been able at most to render temporarily a little less strongly positive. I have seen so many of these resistant Wassermann-positives become Wassermann-negative as the result of further treatment, that in my opinion systematic treatment should be continued for at least three years before we can think of relegating the patient to the class of the permanently Wassermann-positive. It is possible that such a patient harbors spirochetes in his viscera and that occasional short courses of treatment maintained for a number of years will serve to prevent the manifestation of any syphilitic lesions; but further energetic treatment of the kind that is demanded in the first years of his infection seems to me no longer required.

Second, a class of elderly patients in whom, as the result of a thorough clinical examination, a strongly positive Wassermann reaction is discovered, as it were, by accident. These patients present no clinical evidence of syphilis whatever; they give no history of infection, or they may perhaps recall a genital sore of thirty years before, and perhaps present a genital scar, for which they never received treatment and from which they never observed any effects. What is the proper line of conduct to pursue with these old untreated asymptomatic Wassermann-positives? The question, in my opinion, resolves itself into a judicious weighing of possibilities and balancing of evils. The man who has carried his spirochetes for thirty or forty years without even being aware of his condition may well be allowed to carry them undisturbed for the rest of his days. When we consider the prognosis of his case, we must admit the possibility that he will die of cerebral hemorrhage as the effect of syphilitic changes in his arteries at the age of 60 or 65 instead of going on to the full span of life. But we cannot be sure even of that; and against this simple possibility we must weigh the great distress which a prolonged course of antisyphilitic treatment necessarily involves and, in the end, the grave doubt as to the ability of such treatment to eradicate the spirochetes. The asymptomatic Wassermann-positive who is well past his fiftieth year, as a rule, should be let alone.

With regard to this class of case as well as with the somewhat younger syphilitic who remains Wassermann-positive in spite of the most energetic treatment, yet presenting no evidence of visceral syphilis, the question arises whether we may not be dealing with a condition analogous to that of the healthy carriers of meningitis, diphtheria or typhoid bacilli; whether there is not a class of spirochete carriers who, while harboring the germs, are themselves immune to their effects. There is a growing conviction among syphilologists that there is indeed a class of harmless spirochete carriers, harmless to themselves, because the spirochetes are merely saprophytes in their host and harmless to others, because, unlike the carriers of meningitis, diphtheria and typhoid, their germs have no way of leaving their host to infect others. However, we must not too lightly

1. In yaws the Wassermann reaction is always positive, in nodular leprosy generally; but with these diseases a question of differential diagnosis from syphilis is not likely to occur, at least in this country.

assume that a given case, asymptomatic and Wassermann-positive, belongs to this class till we have really subjected the patient to adequate treatment and by examination of the spinal fluid excluded the possibility of a still latent syphilis of the central nervous system.

As an aid in the diagnosis of syphilis and as a means of showing the necessity for further treatment in our cases, the Wassermann reaction has enormously enhanced the general prognosis of syphilis.

THE ORGANIC ARSENIC COMPOUNDS

We come now to the third achievement: the employment of the organic arsenic compounds to which the name of arsphenamin has been officially assigned. The extravagant hopes that were entertained ten years ago when this remedy was first announced have not been realized, and in the disappointment of our expectation that a single injection of arsphenamin would permanently sterilize the patient infected with spirochetes, the pendulum has swung too far and we have lost sight of the fact that a complete spirochetal sterilization is, indeed, a frequent achievement. While, in the great majority of cases, prolonged treatment is necessary, every syphilologist can point to some cases in which the disease, attacked in its initial stage, has been eradicated by a single injection or a single short course of injections. The proof of cure in these cases rests on the permanence of the negative Wassermann reaction, on the freedom from symptoms extending already up to nearly ten years, and finally on the frequent occurrence of reinfection with syphilis in these cases. When we consider the enormous chronicity of syphilis, the fact that lesions may occur after an interval of freedom from symptoms lasting for thirty or forty years, it is evident that freedom from symptoms alone cannot be considered a proof of cure. The provocative arsphenamin injection is a futile and often misleading procedure.² The only positive proof of cure is a fresh infection. As long as the patient is syphilitic he cannot acquire syphilis; he is immune to a fresh infection with spirochetes. Conversely, the occurrence of a fresh infection is a proof that he was free from syphilis. In the old days, reinfections of syphilis were such rare events that many syphilographers questioned the possibility of their occurrence, and sought to explain the symptoms as relapses in a syphilitic; but the best authorities, including Fournier, finally recognized reinfection as a possible, though rare, accident. Since the introduction of the new remedies, reinfections with syphilis have become a relatively frequent event. Such a case occurred in my own practice only a few days ago:

The patient had acquired a cephalic chancre in 1902. He was treated by pills, which he continued taking intermittently until I saw him in 1914. At that time he presented several patches of a scaling serpiginous syphilid on the neck and scalp, and a positive Wassermann reaction. A course of arsphenamin and mercury by injection rapidly removed his lesions and brought about a negative Wassermann reaction. During the year he received three more courses of treatment, the Wassermann reaction remaining negative. During the next two years he was under observation without treatment, and his blood, examined at intervals, was negative. He was discharged in April, 1917. I saw him again, January 17 of this year. He had been venereally exposed about December 12, and four weeks later noticed a sore on the prepuce. Five days later when I saw him he presented a lesion which no syphilologist would have hesi-

tated to pronounce a syphilitic chancre. Shape, border, floor and induration were characteristic, and on dark-field examination spirochetes were found abundantly present. The Wassermann reaction was negative.

Such occurrences must in the nature of the case be extremely rare. By the time a man has been cured of his syphilis, he has grown older and usually wiser. He is less likely to expose himself quite so carelessly as before; he has had a severe lesson which has sobered him; perhaps he has married. The cured syphilitic, in short, is not so good a target for infection as he was before. But where in the old days we had one case of reinfection we now have a hundred. Every one of these cases, of course properly authenticated, is an absolute proof of the efficacy of treatment, and their greatly increased number in recent times is a proof of the superiority of our present methods over the past. The prognosis of syphilis has been incalculably enhanced by the new remedies.

With this statement of a strong conviction we must be content. It is impossible to give figures of comparison. We know that the majority of syphilitics were symptomatically cured by the use of mercury alone. But we see our hospitals and asylums still filled with the victims of syphilis uncured by this treatment.

BENEFITS OF IMPROVED PROGNOSIS

The recent additions to our knowledge have made it possible to attack the disease by prophylaxis at the moment of infection; to make an infallible diagnosis before the system is swarming with spirochetes; to recognize the necessity for further treatment even in the absence of symptoms; to detect the disease in the central nervous system before clinical symptoms are manifest, and, finally, in arsphenamin, have given us a remedy incomparably superior to mercury in speed of action as well as in efficacy.

It is inconceivable that the next generation will not reap the benefit of the improved prognosis of syphilis.

1 West Seventieth Street.

THE RÔLE OF CARBOHYDRATES IN THE TREATMENT OF TOXEMIAS OF EARLY PREGNANCY*

PAUL TITUS, M.D.

GEORGE L. HOFFMANN, Ph.D.

AND

M. H. GIVENS, Ph.D.

PITTSBURGH

Nausea with occasional vomiting early in pregnancy is undoubtedly a manifestation of mild toxemia, but the condition is so familiar to every one that it attracts little attention. Patients often demand medical care because they are seriously annoyed by their "morning sickness," without arousing much concern on the part of the physician. On the other hand, many patients, because they think that this condition is to be expected during pregnancy, fail to seek advice until vomiting has progressed to the point at which it may be classed as "pernicious" or "intractable."

Despite the fact that fairly severe toxemia is not at all uncommon, and that mild toxemia is met con-

* Read before the New York Obstetrical Society, Jan. 13, 1920.

* From the Department of Obstetrics, and the Research Laboratories of the Western Pennsylvania Hospital.

2. Pollitzer, Sigmund, and Spiegel, L.: The "Provocative" Wassermann Test, *Am. J. Syph.* 3: 252 (April) 1919.

stantly, there are many problems presented in this connection that are still without adequate explanation. There are, for instance, the questions of when to interfere and when not to interfere; which is to be a mild case of vomiting that may be expected to cease spontaneously, and which is to become a case of uncontrollable vomiting with inanition, acidosis, dehydration and death; and, in fact, why women should suffer at all during pregnancy from even mild nausea. Undoubtedly there is a relationship between the milder and the graver types of toxemia of early pregnancy, and there is a problematic relationship between these toxemias and those of later pregnancy which we know as acute yellow atrophy of the liver, preeclamptic toxemia, and eclampsia.

It seemed reasonable, on this account, to hope that a study of the milder types of toxemia might disclose important facts regarding the origin of the more serious toxemias. Despite the tremendous amount of work that has already been done along these lines, we felt impelled to begin this study in order to explain, if possible, the success of a purely empiric line of treatment which has given unusually good results in our clinic.

A series of seventy-six cases of toxemia of early pregnancy was treated along certain definite lines. That is to say, our method of approaching this condition underwent a gradual process of development during a period of about five years, one point suggesting another, until the time came when all our patients were subjected to a consistent, well-outlined course of treatment which varied only in being more or less rigid according to the severity of the woman's illness. Further attention to certain details made it possible to apply the same general principles that had been developed to more profoundly toxic conditions, not only during early pregnancy but also late in pregnancy, still obtaining beneficial results with progressively fewer failures.

THEORIES REGARDING ETIOLOGY OF TOXEMIA OF EARLY PREGNANCY

A review of the extensive literature on this subject, with the ingenious theories that have been advanced to explain all toxemia of pregnancy, is the best possible demonstration of the fact that no single idea is sufficiently comprehensive to cover this unquestionably complex matter.

Certain unknown toxic substances are supposed to be elaborated somewhere in the metabolism of a pregnant woman. The presence of these substances in the body is considered to be the cause of the vomiting and of the pathologic changes that result if the diseased condition is prolonged. There are four main theories as to the source of these toxic substances. The first is that they are of gastro-intestinal origin and akin to an ordinary autointoxication; the second, that they occur as the result of disturbances in the various glands of internal secretion; the third, that they are of fetal origin; and the fourth, that they result from disturbance in liver function. Dirmoser¹ was the first to assert that these toxins were the result of intestinal putrefaction, and it is still agreed that autointoxication may be an exciting cause of pernicious vomiting of pregnancy. The thyroid, the parathyroids, the suprarenal glands and the ovaries have all been credited with responsibility without actual confirmatory evidence, while the fetus itself, because of its demands on

the mother and because it casts off foreign protein into the maternal blood stream, has been plausibly blamed. So far as the fourth theory is concerned, it is manifest that liver function is disturbed, but the theory offers no explanation of the manner in which this occurs. Disturbance in liver function might as readily be an effect as a cause of toxemia.

Considerable work has been done by Williams,² Stone³ and Ewing⁴ on the pathologic changes in the liver and their significance, and the work of these authorities on maternal metabolism is familiar to every one. This is especially true of that done by Williams,⁵ who still classifies vomiting of pregnancy as reflex, neurotic and toxic. Reflex and neurotic types fall into one of two main groups, while toxic vomiting constitutes the other, and Williams distinguishes between the two by changes in the relation of the ammonia nitrogen to the total nitrogen of the urine, this being termed the ammonia coefficient. It is hardly necessary to consider in detail the questions which Williams' views have brought up, because their importance aroused marked interest, and at the same time no little controversy. No classification should be too sharply defined, and it is probable that all neurotic vomiting of pregnancy has an underlying element of toxemia. On the other hand, toxic vomiting of pregnancy is usually accompanied, in its beginning at least, by a certain degree of neurosis. In many cases, particularly if seen in the early stages, it remains to be determined, therefore, whether it is the neurosis or the toxemia which predominates in the combination. Symptomatically the two groups are alike, because even a simple starvation is accompanied by acidosis, inanition, and another most important factor, dehydration.

While it is true that no one of these various theories is sufficient to account for the origin of the toxemia of pregnancy which is manifested by nausea and vomiting, nevertheless they offer many clues which must be of value at some time in solving this perplexing problem. We have merely endeavored to follow some of these clues.

DEVELOPMENT OF TREATMENT FROM A DIETETIC STANDPOINT

It has been recommended for some time, especially by Dr. Whitridge Williams, that women suffering from nausea, or the so-called "morning sickness," be directed to eat some simple thing, such as one or two soda crackers and a glass of water, before arising in the morning. Williams suggests that the mental effect of this simple course is important; but benefit follows so often and an elaboration of this procedure gives such significant results that it must be physical rather than psychic in its action.

The first nausea of pregnancy usually affects the patient early each day, soon after she arises. This is after the longest period of fasting in the twenty-four hours. An over-night fast can produce only moderate hunger but any hunger may be considered mild starvation. If eating before making any exertion relieves this morning nausea, it is obvious that there is a relation between starvation and the occurrence of the nausea.

Having relieved some patients of "morning sickness" by directing them to eat either the crackers and

water or their regular breakfast in bed, it was a natural step to suggest to those patients who had nausea throughout the entire day, either with or without vomiting, that they eat regularly between meals as well as at the usual mealtimes. It is necessary to specify what and when the patient shall eat, because it is by the use of carbohydrates that the best results are obtained. Excessive amounts of proteins are not demanded or well tolerated, and, indeed, the higher the protein intake the more rapidly does the toxemia progress from bad to worse. This is probably due to the greater nitrogen elimination made necessary by protein metabolism and intestinal putrefaction, and also because of the proportionately lessened carbohydrate intake.

GENERAL OUTLINE FOR DIET HIGH IN
CARBOHYDRATES

Article of Diet and Amount	Percentage of			Calories
	Protein	Fat	Carbo- hydrates	
7:20 a. m.				
2 soda crackers.....	1.4	1.2	10.2	55
Breakfast, 8 a. m.				
Stewed prunes (6 large).....	1.4	...	47.0	200
or 1 baked apple.....	0.4	0.5	14.0	64
3½ oz. oat-meal.....	3.8	1.4	17.8	101
or 3½ oz. cream of wheat.....	3.0	0.2	19.1	93
with ½ oz. sugar and 1 oz. cream.....	0.8	5.7	16.4	122
Cup chocolate with sugar.....	4.1	7.5	22.0	325
2 slices toast.....	5.8	...	32.0	140
1 oz. honey.....	25.0	101
10:30 a. m.				
2 slices toast.....	5.8	...	32.0	140
or 2 crackers.....	1.4	1.2	10.2	55
1 glass milk.....	6.2	7.0	9.4	128
Lunch, 12:30 p. m.				
Cream of celery soup.....	1.8	2.5	4.5	50
or potato soup.....	8.7	7.1	30.7	225
4 crackers.....	5.6	4.8	40.8	144
2 slices bread and butter.....	5.8	...	32.0	140
Lettuce, ½ head.....	1.2	0.3	2.9	20
1 cup custard.....	5.1	7.7	32.0	100
or 1 cup cornstarch pudding or 1 cup apple tapioca.....	0.2	0.07	23.0	100
or 1 cup ice cream.....	4.9	6.4	23.4	172
or 3 oz. gelatin with cream and sugar	5.0	5.7	29.0	187
"Tea," 4 p. m.				
Tea with sugar.....	10.0	40
2 slices toast.....	5.8	...	32.0	140
1 slice sponge cake.....	6.3	10.7	60.0	384
Dinner, 6:30 p. m.				
1 cup cream of pea soup.....	3.6	0.7	7.6	50
or other soups as at lunch				
2 crackers.....	1.4	1.2	10.2	55
2 slices toast.....	5.8	...	32.0	140
Baked potato, sweet or white (large).....	1.7	...	16.0	100
or 3 oz. rice.....	1.7	0.1	20.5	92
3 oz. stewed carrots.....	0.9	0.3	7.5	50
or 3 oz. beets.....	1.9	0.1	6.1	33
Desserts as at lunch				
or 1 oz. dates.....	0.7	0.9	26.0	116
or 1 oz. raisins.....	0.8	1.0	24.0	100

2 slices bread.....	5.8	...	32.0	142
or 2 soda crackers.....	1.4	1.2	10.2	57
1 glass milk.....	6.2	7.0	9.4	128

This point may be questioned by those who agree with Lynch.⁶ He emphasizes in a recent publication the importance of diet in toxemia, but urges absolute restriction of sweets and fruits, giving a diet of proteins and a limited amount of fats in what he calls the hyperacidity group of cases. Hyperacidity or sub-acidity will have little influence if gastric lavage is employed with any regularity, and the improvement in Lynch's cases was probably due more to the fact that he administered large amounts of glucose and soda by rectum, than to the dry solid diet which he considered essential. It is common knowledge that excessive meat eating is inadvisable during pregnancy, and absolutely to be interdicted in such a toxemia as a preeclamptic state.

The usual outline for the day was a soda cracker breakfast before rising, a light breakfast at the regular time, unsalted soda crackers and milk in the middle of the morning, and a light lunch without meat or pastry at lunch time, the dessert being cornstarch or rice pudding or custard. Afternoon tea with arrow-root biscuits or bread and butter sandwiches was followed at the usual time by a light dinner or supper similar to the luncheon, with some sweets and possibly raisins or dates for dessert. A bowl of bread and milk at bedtime, and some crackers and water on the bedstand for use during the night, complete the twenty-four hour schedule. This was usually sufficient to relieve an ordinarily mild case of nausea and vomiting, if due attention was also paid to elimination by the bowels. It will be noticed that this is not a strictly protein-free diet, but rather, a diet high in carbohydrates.

The accompanying table is presented for the purpose of demonstrating the preponderance of carbohydrates in the diet which has been suggested for these patients. It is scarcely necessary to point out that this is merely a general outline, and that considerable variety is possible if this outline is used as a working basis in the arrangement of menus. It is by no means essential that proteins and fats should be entirely eliminated. Glucose and soda solution supplements the carbohydrate intake to the extent of about 10 gm. of glucose if the patient is given, as is directed below, 1,000 c.c. of 10 per cent. glucose and 2 per cent. sodium bicarbonate solution per day.

More aggravated cases of vomiting may result in spite of this dietetic treatment by direct progression from the one condition to the other, or because the patient fails to carry out these directions. Women whose vomiting is becoming progressively worse require more detailed care and observation. At first all food should be withdrawn for a period of from twenty-four to thirty-six hours in order to give the stomach a complete rest. Gastric lavage should be carried out two or three times daily to remove food residue, bile and mucus, because these patients all present a certain amount of reverse peristalsis. Furthermore, such cathartics as magnesium sulphate are necessary in order to reestablish peristaltic movements downward, and to open the bowels. This may be passed in through the tube, and is usually retained if the stomach has been washed out before its introduction. Enteroclysis of glucose and soda solution, as well as the usual rest in bed is required, and the employment of sedatives in the form of bromids and chloral is customary when indicated.

After the initial period of rest, during which the vomiting usually subsides, the stomach requires reeducation in precisely the same way that it does in any person who has been slowly starving for days or weeks. Either stomach is intolerant of food and would reject any great amount put into it. Consequently small amounts of nourishment are given at frequent intervals after the period of rest seems to have accomplished its purpose. An ounce to an ounce and a half of whey, peptonized milk, skimmed milk and vichy, or buttermilk are given alternately with two ounces of 10 per cent. glucose and 2 per cent. sodium bicarbonate solution every two hours. By mouth or by rectum an effort is made to give the patient at least one quart of the latter solution daily; but if her condition is at all urgent, plain glucose is

6. Lynch, F. W.: Treatment of the Severe Vomiting of Early Pregnancy, J. A. M. A. 73:488 (Aug. 16) 1919.

given by intravenous injection, and repeated as often as indicated. Wilder and Sansum⁷ have demonstrated that as much as 0.8 gm. of glucose may be given intravenously per hour per kilogram of body weight without causing a glycosuria. They have given a large number of such injections, as have Erlanger and Woodyatt⁸ in their work on the intravenous injection of glucose in shock. Litchfield⁹ has used intravenous injections of glucose in pneumonia, and we have employed it extensively in our work on toxemia, including eclampsia, as well as in normal pregnant women in connection with some research work to which we shall refer presently. In none of the work of the authorities referred to nor in our clinic have there been serious reactions, and with proper technic no reaction should follow. One of the chief precautions necessary is to give the injection slowly. We usually allow one-half hour to inject from 15 to 20 gm. of glucose in 250 c.c. of water. It is also absolutely essential that glucose for intravenous injection should not be a commercial product, but chemically pure, and the solution should be sterilized in an autoclave.

If patients find glucose hard to tolerate, and glycosuria appears, we do not feel that this should influence the treatment more than to indicate a need for a reduction in the amount given, and the intravenous injections may be repeated as often as necessary, while the ingestion by mouth may be continued in lessened quantity. Litchfield has referred to the importance of dehydration in all toxic or starved persons, and this cannot be too strongly emphasized. Water is urgently demanded, and should be given frequently in small amounts during the initial period of rest referred to above. If it is rejected from the stomach, it must be given by enteroclysis or by intravenous injection. In the latter case it is usually given by being used as the solvent for the glucose which we consider necessary.

Ordinarily, by the third or fourth day these patients may have such soups as cream of celery or purée of potatoes added to their diet, with stewed fruits, corn-starch pudding, or ice cream, still continuing the glucose and soda by mouth and by bowel. Crackers, milktoast, cream of wheat and various other gruels, custards and sugar are added next, the important feature of the entire course of treatment being a strict adherence to the regimen laid down, and a careful observation of details. An early return to a substantial diet high in carbohydrates is soon accomplished in most cases.

This lengthy explanation of the dietary procedure that has given the best results in our work has been made solely to point out the reasons for believing that a deficiency in carbohydrate intake is an important factor in the etiology of toxemia of pregnancy. So many of the facts that we have outlined, and so many of the suggestions for treatment which we have made, are known in a general way that it might seem as though nothing new had been offered. This is largely true; but the fact remains that these points, many of them thoroughly familiar to the profession, have not been correlated and put into practice in anything more than a haphazard way, and then are used empirically.

Glucose and its usual concomitant soda are ordinarily employed on the ground that there is an acidosis present. It must be remembered, however, that acidosis is a symptom and not a distinct entity in itself, and that it is difficult to be contented with the mere treating of symptoms.

APPLICATION OF THE CARBOHYDRATE DEFICIENCY THEORY

Observing that the free use of carbohydrates in various forms was followed by a large measure of success in toxemia, it was only natural to seek an explanation of this. It was felt that any sound reason which might be offered for the results we were obtaining might give light on the origin and cause of toxemia of pregnancy.

Toxemia of pregnancy is a condition presenting vastly different degrees of severity in different persons, and also some variation depending on the manner in which such organs of the body as the liver, kidneys and gastro-intestinal tract behave under the strain of pregnancy. On these points quite definite statements may be made; but the influence of the various glands of internal secretion is still more or less problematic.

Pregnancy as a condition is a constant of a woman with a growing fetus within her uterus. There must be some variable which affects different women in this state in the different ways just outlined. This variable can hardly be individual or personal resistance to this strain, although that may play a part, for it is quite impossible to predict from a woman's general physical condition or appearance at the time her pregnancy begins whether or not toxemia is to be a serious menace to her. Furthermore, that toxemia which develops at this time is peculiar to pregnancy and not more than distantly related to those which accompany nephritis, diabetes, etc.

Toxemia of pregnancy is favorably affected by regulation of the diet, and there is no one thing in the daily life of various persons that is so variable as their diet. So-called "auto-intoxication" occurs in both men and women who habitually overeat, especially if they overindulge in proteins. Toxemia of pregnancy may be thought of as being markedly influenced by an improperly balanced diet, and at the same as being peculiar to pregnancy, because the establishment of a growing fetus within the uterus has made a new and profound demand on the metabolism of the mother.

For fear of being thought faddists in this matter of the influence of diet, we are anxious to reiterate that we believe all four of the main theories outlined earlier in this paper have a direct bearing on toxemia. It is a complex matter, and undoubtedly the organs of internal secretion, the demands of the growing fetus, the condition of the gastro-intestinal tract, and lastly, the condition of the liver, all have more or less influence, either directly or indirectly. The balance between normal and abnormal pregnancy is so delicate, however, that it requires only some slight disturbance to upset this equilibrium. We believe that a deficiency in carbohydrates is usually the disturbing element, and that the mechanism by which carbohydrate starvation produces toxemia of pregnancy is quite definite.

Carbohydrates are not only well tolerated but actually demanded in the metabolism of a pregnant woman. This carbohydrate demand is apparently in excess of that of ordinary life, and may be explained

by the fact that the growing fetus urgently requires unusually large amounts of glycogen. This subject has been closely investigated by Slemmons in his work on "The Nutrition of the Fetus."¹⁰ He finds that the fetal tissues synthesize their protein from material in the fetal blood which has been acquired by diffusion from the blood of the mother, and that fats and lipoids do not cross the placenta but are almost certainly manufactured in the body of the fetus. They are manufactured from carbohydrates which have passed through the placenta from the maternal blood stream, and the fact that Slemmons found a slightly higher mean glucose value on the maternal side than on the fetal side indicates the mechanism by which a steady flow of glucose may be and is maintained toward the fetus. It not only uses it but stores it, the placenta being the glycogen storing organ until the fetal liver can function in this capacity, according to the investigations of Lockhead and Cramer.¹¹ Glinke¹² and others have shown that glycogen is especially abundant in fetal tissues, and McAllister¹³ has demonstrated by his analyses that glycogen, present in the uterus and tubes independent of pregnancy, is most abundant at the time of childbirth, also being especially marked in the placenta.

This demand is an abrupt and unaccustomed drain on the patient, who is called on at no time other than during pregnancy to supply glycogen at this rate to any tissue or organ of the body. The uterus is enlarging rapidly, and in its muscular hypertrophy is making an extra demand for glycogen, while the fetus is growing far more rapidly than the child ever does in its extra-uterine life, thus being another example of unusual hypertrophy.

That the placenta is responsible for this glycogen demand, its object being to obtain this for the benefit of the fetus, is shown by the fact that any condition, such as twin pregnancy, syphilis, or hydatidiform mole, in which there is placental overgrowth, is usually accompanied by undue toxemic manifestations. That is to say, many of these patients give a history of profound or prolonged nausea and vomiting, and some of them exhibit the more serious phases of intoxication. Women with hydatidiform mole, in which there is a proliferation of chorionic tissue, have given us the history of marked nausea and vomiting, beginning shortly after impregnation and continuing up to the time of operation. There are on record¹⁴ a number of cases of eclampsia occurring in the presence of a vesicular mole with no fetus present, and this phenomenon is quite readily understood if this theory of carbohydrate demand and supply be accepted.

If the extra glycogen demand of pregnancy is met by a diet containing a liberal carbohydrate supply, there should be little or no trouble from toxemia. If the demand is not met, the liver will be called on as the glycogen storing organ of the body to make up the deficit. Any glycogen storage in the muscles of the body is only temporary, and here again the liver is depended on for a reserve supply. Glycogen supply to the muscles must be maintained because it is consumed in the functioning of a muscle, so that rest in

bed should be valuable treatment from the standpoint of conservation.

As the liver gives up more and more of its glycogen without adequate replacement, whether this is due to fetal demand or to ordinary starvation, a certain amount of fatty replacement, and eventually degeneration, occurs in those cells which originally stored the glycogen. Pflueger¹⁵ has found that glycogen disappears almost entirely during experimental starvation, to be rapidly reformed after rich carbohydrate feeding. The experimental production of a fatty infiltration of the liver cells by means of phlorizin or by chloroform poisoning is familiar to all physiologists, and Rosenfeld,¹⁶ in 1902, stated that after producing this lesion by means of phlorizin he found it possible to clear up the fatty infiltration in one day by giving the animal a meal rich in carbohydrates. The recent publications of Davis, Hall and Whipple¹⁷ have been a most comprehensive contribution to this subject. These authors tested the effect on the liver of various poisons under varying circumstances, and found that they were far more toxic and produced yellow atrophy of the liver more readily if the dogs utilized in the work had been fed a diet high in proteins than if they had been living on a carbohydrate diet. Furthermore, the ingestion of carbohydrates in various forms caused the central necrosis of the liver lobules in poisoned dogs to disappear much more rapidly than in control animals. Roger¹⁸ has made the contention that the liver loses its detoxicating power if made glycogen-free by hunger or other experimental methods, and conversely that all substances introduced produce a less toxic action if the glycogen content of the liver is increased by the simultaneous administration of glucose.

In pregnancy there is at first a relative hunger, brought about by a sudden increase in demand rather than a decrease in supply of certain food elements. Hunger or starvation tends to make the stomach intolerant of food, and the lack of supply is thus promptly augmented. It is, however, a specific starvation or deficiency with which we are concerned, namely, that of carbohydrates. If an exhaustion of the stores of carbohydrates in the body is combined with dehydration of the tissues, acidosis is certain to result. Liver functions are seriously impaired under such circumstances, and the body is flooded with toxins. No food or water is being taken, the patient is feeding on her own body tissues, and thus presents the typical picture of so-called "pernicious" or "intractable" vomiting of pregnancy.

In an article appearing while this was in preparation, Duncan and Harding¹⁹ of Montreal have reported work done along practically identical lines as those of ours, with equally favorable results. They report a series of seventy cases, to which may be added seventy-six that we have to report. The fact that similar theories were formulated and common results obtained in a total of 146 cases, by two groups of investigators

working independently, does much to strengthen the force of our argument.

They, too, suggest that a deficiency in carbohydrates is largely responsible for toxemia of pregnancy. We do not, however, agree with them in respect to the physiologic working of what is perhaps the most important point in the carbohydrate deficiency theory. The typical pathologic changes in toxemia of pregnancy are not due, apparently, to the fact that the fetus is greedy of unsaturated fat, for, if correct, this could have little or no bearing on a fatty degeneration of the liver. Nor is it merely because a moderate degree of fatty degeneration of the liver occurs as the result of a few hours' fasting.

We believe that this lack of glycogen in the liver is the result of a direct demand on the part of the fetus for glycogen. This call for glycogen is sent to the liver precisely as it would be from any organ requiring glycogen for consumption or combustion, and its place is taken in the liver by fat deposits. The mechanism by which a vicious circle may be established is quite evident.

REVIEW OF CASES

It has been found convenient for the purpose of study to separate these patients into groups according to the severity of the symptoms at the time each woman was first seen and treatment begun. For the sake of brevity, the record of the cases will be summarized, with a mere statement of the outcome. Women who suffered from nausea without vomiting are not included in this series. All were less than eighteen weeks pregnant.

GROUP 1.—This group is composed of patients complaining of irregularly occurring nausea and vomiting. This appeared most often in the morning, but might be troublesome to the patient at other times during the day. Dietetic treatment as outlined above was sufficient for most of these patients, although a few, especially latterly, were directed to take 1 or 2 ounces of 10 per cent. glucose and 2 per cent. sodium bicarbonate solution at three hour intervals.

Thirty-two patients appear in this group. Twenty-nine of them showed immediate improvement, whereas three required from seven to fourteen days for relief. All obtained permanent relief. One patient required appendectomy.

GROUP 2.—Twenty-nine women comprise these cases. In them the vomiting was persistently growing worse, and nausea was constant. Considerable loss of weight occurred in two, while one woman was slightly jaundiced. It developed later that two of these patients had twin pregnancies. Both of them fell into labor prematurely, and one of them showed some symptoms of toxemia near the end of her pregnancy. Prompt relief from nausea and vomiting was obtained by our treatment in twenty-three cases, while five patients recovered more slowly, as in Group 1. One patient failed to show improvement, and suffered from constant nausea with considerable vomiting, occasionally relieved for only a short time. This woman had been a trained nurse and was the only one of this group who did not go to the hospital. She was nursed by a sympathetic friend who would carry out some of the disagreeable features of the treatment with great vigor, only to relax her efforts as soon as the patient showed temporary improvement. Nausea never completely abated, but pregnancy continued to term.

GROUP 3.—This is composed of fifteen cases of the most serious type. All of these patients exhibited acetonuria, the majority having albumin and casts in the urine. Many were jaundiced and all were emaciated, while food and water were being retained by none. All of the patients were seen in consultation, and immediate therapeutic abortion was expected by most of the attending physicians. Fourteen of these women recovered entirely within from seven to fourteen days.

A therapeutic abortion was performed on one patient. This woman had been under treatment for five weeks in a hospital where a religious objection to abortion existed, and when sent to my service she was deeply jaundiced and emaciated. She was then three months' pregnant and had developed a multiple neuritis with paresthesia of hands, arms, feet and legs. Knee-jerks were absent, and she complained of intense pain on attempts to move her legs. In view of her condition and on the advice of the obstetrician who had been caring for her, an abortion was performed. A transfusion of blood was deemed necessary a few days later on account of her general condition, and she was obliged to remain in the hospital for weeks. The neuritis has not entirely left her after a period of two years, but she has since gone through a pregnancy with success, being one of the patients listed in Group I as having been treated for mild toxemia of early pregnancy.

PRELIMINARY REPORT OF CHEMICAL AND EXPERIMENTAL INVESTIGATIONS

Being convinced from clinical experience of the potency of carbohydrates in the treatment of toxemia of pregnancy, and having theorized as to the physiologic mechanism of their action, we have endeavored to prove this by certain experimental and chemical investigations. We desire to make a brief preliminary report of this work at this time, and plan to follow this paper with one that shall deal with our investigations and their application to toxemia of both early and late pregnancy.

We are attempting to produce the pathologic lesions of toxemia in pregnant experimental animals, and have had moderate success. This work is being continued, and if successful will be extended.

The procedure of our chemical investigations has been based on two established facts, namely, (1) the liver is the carbohydrate storage organ of the body, and (2) according to necropsy findings in fatal toxemias, the liver undergoes fatty degeneration. It is evident that fat is first substituted for glycogen in the cells, and finally when liver function is seriously impaired by glycogen depletion, this pathologic change may well be classed as an actual degeneration.

On this basis we have endeavored to devise a test for liver efficiency and deficiency. We have established a normal time curve of the liver's ability to store a definite amount of glucose given intravenously to normal pregnant women. A study of similar curves in cases of toxemia points to the conclusion that the prognosis is good if the liver can store within thirty minutes as much as from 75 to 105 mg. of glucose per hundred cubic centimeters of blood, this ratio of storage being approximately equivalent to, or slightly more rapid than that of a normal pregnant woman. If only 30 to 40 mg. of glucose can be handled, a grave condition is faced, this being much less than normal. We have reasoned that a need for carbohydrates exists in both instances. In the first the liver has been taxed but is able to restore itself if carbohydrate is supplied, whereas in the second case the depletion of glycogen and the deposit of replacement fat has been so extensive that the cells have lost their function, and the damage may be termed necrosis or degeneration.

The cases we have studied include eclampsia, pernicious vomiting, nephritis complicating pregnancy, chorea, and one case of accidental separation of the placenta with kidney involvement. A control series of tests is being carried out on all patients after recovery, and these, without exception, have corresponded to the normal cases.

CONCLUSIONS

1. The problematic relationship between mild and profound toxemias of pregnancy warrants a study of the former in order to gain information regarding the latter.

2. The development of a course of treatment, the success of which seemed to depend on the use of carbohydrates in large amounts, led to the assumption that a deficiency in carbohydrates has an important bearing on the origin of toxemia of pregnancy.

3. Carbohydrate deficiency during pregnancy is of twofold origin; (1) a relative deficiency due to an unexpected demand for glycogen on the part of the fetus and the uterus, and (2) an actual deficiency, augmented in the presence of nausea and vomiting, from lessened carbohydrate intake.

4. Carbohydrate deficiency in the maternal organism causes a glycogen depletion of the liver, because this is the organ in which carbohydrates are stored for use as needed.

5. There is experimental evidence to show that liver function is impaired and the body flooded with toxins after carbohydrate starvation.

6. Pathologic changes in the liver lobules which are similar to those of fatal toxemias of pregnancy can be produced experimentally by the use of certain chemical poisons. These changes can be made to disappear rapidly by the ingestion of carbohydrates.

7. Mild cases of nausea and vomiting may be controlled by so regulating the diet that there is a preponderance of carbohydrates, and an avoidance of more than short intervals of fasting by the taking of food more frequently than under ordinary circumstances. This increased carbohydrate intake should be augmented by giving the patient from 8 to 16 ounces of 10 per cent. glucose and 2 per cent. sodium bicarbonate solution daily by mouth. This may be given in 1 or 2 ounce doses.

More severe cases require more rigid attention. After an initial period of rest, gastric lavage and the introduction of saline cathartics through the stomach tube, small amounts of liquid food are allowed alternately with from 1 to 2 ounces of the glucose and soda solution, described above, every two hours. By mouth or by bowel it should be possible to give the patient 1 quart of this solution daily.

In the seriously toxic patients the treatment is pushed even more vigorously with the addition of intravenous injection of from 15 to 25 gm. of glucose in from 250 to 300 c.c. of water. This is given from one to three or more times daily, according to the needs and response of the patient. The injections should be made in close accordance with the directions in the body of this paper. Other treatment is carried out along much the same lines as that for the second group.

8. Not only is intravenous injection of glucose solution a valuable therapeutic measure, but the rate of its absorption and storage by the liver is an index of liver efficiency which is of prognostic value. More rapid storage than normal is favorable because it indicates that the liver, depleted as it has been of glycogen, is nevertheless still able to restore itself. Storage which is slower than normal offers an unfavorable prognosis, since this is evidence that liver efficiency is impaired. Our clinical evidence regarding these views is still too limited to permit a definite conclusion, but our experience thus far has been entirely confirmatory.

THE THERAPEUTIC USE OF CARBON DIOXID AFTER ANESTHESIA, AND OPERATION *

YANDELL HENDERSON, PH.D.

HOWARD W. HAGGARD, M.D.
NEW HAVEN, CONN.

AND

RAYMOND C. COBURN, M.D.
NEW YORK

There is ample experimental evidence that inhalation of carbon dioxid, properly diluted with air or oxygen, should be a therapeutic agent of great potency. In fact, however, aside from the indirect use of this gas in the rebreathing methods of anesthesia, particularly with nitrons oxid, inhalation of carbon dioxid is not used in surgery. Likewise in internal medicine it is not employed, except perhaps in the Nauheim bath treatment of cardiac conditions; and here there is no agreement as to whether or not the inhalation is a factor.

This lack of use is the more striking when we note the present deficiency in therapeutic agents to stimulate breathing, and the great need for one; for carbon dioxid is Nature's own stimulant to the respiratory center.¹

On the circulation its influence is equally important—particularly on the venous return to the right heart. It is the insufficiency of this return which chiefly gives to postoperative depression its similarity to the effects of hemorrhage. Thus, recovery of the circulation and a rapid return of a normal arterial pressure are the results to be expected from the restoration to the blood and tissues of the carbon dioxid lost during anesthesia and operation.² At least, this is the result which we have obtained.

The reason for the neglect of carbon dioxid is not far to seek. It lies in the fact that without a reliable method and apparatus, or without the acquisition of great skill and tact in a practically unexplored field, the administration of carbon dioxid might be dangerous. Indeed, if insufficiently diluted with air or oxygen, it would be quickly fatal. Doubtless, in the not distant future it will seem almost incredible that progress should have been halted for a long period for want of an apparatus for controlled gas administration. In fact, however, only recently, after ten years of effort in the laboratory where two of us work, has an apparatus

* In the text of this paper we deal only with such degrees of functional depression as commonly occur after anesthesia and operation. Mention should, however, be made here of work done by us during the winter of 1917-1918 which, although itself negative in result, was nevertheless an essential preliminary to this. It was a study of accident cases brought in by the ambulance. It revealed not a single case of "shock," other than hemorrhage or concussion, during ten weeks at a very large and active hospital in a field where such cases would be expected. Apparently this ignis fatuus of physiology is the product—at least in discoverable amounts—only of the battle field and the operating room, arising doubtless on the one from unrelieved pain, hemorrhage or cold, and in the other largely from some element in anesthesia. Our work had the approval of the Surgeon-General of the Army and was carried out at Bellevue Hospital, New York. We take this occasion to express our thanks to the directors of that hospital, to Dr. Charles Norris and Dr. Adrian V. S. Lambert, and to Col. F. F. Russell of the Surgeon-General's Office.

at all suited to clinical use become available; and yet it is very simple. It needs only a single operator; but he must be an expert in the vital signs of anesthesia and of the powerful functional effects of carbon dioxide, and he must at all times be keenly observant of the patient under treatment.

The first apparatus which we employed was, on the contrary, quite complicated, requiring the constant attention of three or four operators. It involved an air blower, electric motor, tank of carbon dioxide, gas meters, and accessory devices,³ and was unsuited, therefore, to general clinical use. It had, however, the experimental advantage that with it any volume of air of any desired percentage of carbon dioxide could be delivered into the mask from which the patient inhaled.

With this apparatus we were enabled, through the courtesy of Drs. John F. Erdmann and Thomas H. Russell, to make, at the Post-Graduate Hospital, New York, what we believe are practically the pioneer observations (excepting those of Cotton⁴ and of Levy⁵) on the effects of administration of carbon dioxide after ether anesthesia and major surgical operations.

Obviously, in order to show the effects of inhalation of carbon dioxide it was essential that we should first establish, as a standard of comparison, how patients usually behave. In this there is considerable difficulty; for, as we found and as indeed every one knows, there are the widest variations according to the length of anesthesia, its depth, preliminary medication, the character of the patient, and the severity of the operation. Below is presented the abbreviated protocol of a case fairly typical of conditions which are, however, frequent:

PROTOCOL OF CONTROL CASE IN WHICH NO CARBON DIOXID WAS ADMINISTERED

W. M., man, aged 34; double hernia; ether administration, sixty minutes.

Time Minutes	Arterial Pressure Mm. of Mercury	
..	132	Before operation
0	...	In bed, after operation
5	120	Gasps and apneas; cyanotic
25	...	Vomiting
30	108	Depressed respiration; cold, cyanotic, pallid skin
55	102	No improvement
65	...	Vomiting
80	110	Signs of returning consciousness

It is here to be seen that, after the patient was back in bed, arterial pressure continued to fall for an hour—to a level 30 mm. below normal. Respiration during this time was notably depressed. The elimination of ether was correspondingly slow.

EFFECTS PRODUCED BY THE INHALATION OF CARBON DIOXID

While other control cases, after operations for appendicitis, hernia, gallstones, etc., showed these features in more or less marked degree, this case, in our observations, is by no means an unusual or extreme illustration of postoperative depression. Using it as a rough standard of comparison, we give the protocols of four cases illustrative of the effects observed under inhalations of carbon dioxide.

3. Parts of a Connell nitrous oxid-oxygen apparatus were used, for the loan of which and for assistance in assembling the whole apparatus we are indebted to Mr. C. A. Mandolini of the Scientific Apparatus Company, New York City.

4. Cotton, F. J.: Acapnia: Its Surgical Importance, Boston M. & S. J. 167: 432, 1912.

5. Levy, Etore: The Clinical Use of Carbon Dioxide with Oxygen, J. A. M. A. 68: 773 (March 16) 1912.

PROTOCOLS OF CASES IN WHICH CARBON DIOXID WAS GIVEN

As it seemed that the benefits hoped for from inhalation of carbon dioxide might possibly involve also grave danger during the inhalation—an anticipation which fortunately was not verified—every precaution was taken to minimize the risk. In all cases the mask was held by one of us (R. C. C.), who has had an extensive experience as an anesthetist, and particularly in the administration of nitrous oxid and rebreathing. At least one other of us kept an uninterrupted watch on the patient, while one kept his eyes on the gages and meters of the apparatus and his hands on its cocks and switches. In this work we are indebted to Dr. W. H. Taliaferro for assistance.

CASE 1.—S. S., man, aged 46; double hernia; ether administration, seventy minutes; postoperative administration of carbon dioxide.

Time Minutes	Arterial Pressure Mm. of Mercury	
..	136	Before anesthesia
0	120	In bed, after operation
1	...	Inhalation of 10 per cent. CO ₂ begun
2	...	Marked respiratory augmentation
3	136	Breathing 35 liters of air per minute
4	160	Inhalation reduced to 6 per cent. CO ₂ Warm, pink skin; Sweating
31	...	CO ₂ stopped; patient fully conscious, but emotionally unbalanced; crying; wanted to get out of bed
33	132	
	136	Four days later

No nausea, vomiting or gas pains; an uneventful recovery.

CASE 2.—R., woman, aged 20; appendicitis and adhesions; prolonged illness; patient weak; ether administration, forty minutes; postoperative administration of carbon dioxide.

Time Minutes	Arterial Pressure Mm. of Mercury	
..	100	Before anesthesia
0	96	In bed, after operation; 10 per cent. CO ₂ started
2	110	
4	130	Breathing 40 liters per minute; CO ₂ reduced to 8 per cent.
18	...	Struggling; breathing 40 liters per minute
19	122	Conscious; CO ₂ stopped
24	122	
	104	Three days later

No nausea, vomiting or gas pains; water given as asked for; an uneventful recovery.

CASE 3.—L. S., man, aged 26; appendicitis and adhesions; ether administration, sixty minutes.

Time Minutes	Arterial Pressure Mm. of Mercury	
..	115	Before anesthesia
0	108	In bed after operation
5	102	Cyanotic
8	96	Inhalation of 8 per cent. CO ₂ begun
15	112	No respiratory augmentation
18	...	Respiration augmented
19	...	Fine pink skin color
21	118	Breathing 35 liters per minute; talks rationally
43	116	CO ₂ stopped
45	112	
	115	Three days later

No nausea, vomiting, or gas pains; allowed to drink water freely; an uneventful recovery.

CASE 4.—A. S., woman, aged 32; exploratory laparotomy and removal of appendix and gallstones; ether administration, fifty minutes; uneventful recovery.

Time Minutes	Arterial Pressure Mm. of Mercury	
..	118	Before anesthesia
0	116	In bed, after operation
1	...	Inhalation of 8 per cent. CO ₂ begun
2	...	Slight increase of respiration; color pale
6	...	Increased respiration
11	126	Breathing 30 liters per minute; pink skin
20	134	Struggling; responds to verbal suggestions
28	136	Answers questions rationally
31	134	CO ₂ stopped
32	...	Vomited a little yellow fluid
180	118	
	120	Four days later

No subsequent nausea, vomiting or gas pains; bowels easily stimulated to function; uneventful recovery.

In these four cases, typical of a total of seventeen so treated, certain points deserve notice:

Within a few minutes after the initiation of the inhalation of carbon dioxid, there was a great augmentation of respiration. Knowing the volume of air delivered to the mask by our apparatus, we could estimate quite accurately the volume of the patient's breathing. A normal well-developed adult at rest in bed breathes from 6 to 8 liters of air a minute. In our control cases, observed without treatment, the volume of breathing was estimated often at less than half as much: hence the common cyanosis. Under the inhalation of carbon dioxid, the volume of breathing was increased to amounts from 35 to 70 liters per minute, volumes corresponding to those which the subjects would have breathed under vigorous physical exertion.

The greater part of the ether was thus rapidly ventilated out of the blood. In from fifteen to twenty-five minutes the patient was conscious, although prone to emotional disturbances, sometimes of anger, but oftener of hilarity. Frequently the patient fell asleep fifteen or twenty minutes after the termination of the inhalation. Presumably there was a slight secondary rise of ether in the blood due to continued diffusion from the muscles, adipose tissue, etc.

Immediately after the operation, the arterial pressure was usually from 5 to 15 mm. below normal, with a tendency to fall further. Under inhalation of carbon dioxid it rose rapidly, sometimes 30 or 40 mm. within four or five minutes; and at the end of the first ten or fifteen minutes it was often 10 or even 20 mm. above normal. It then tended gradually downward again, although remaining above the normal level. After the termination of the inhalation it returned in a few minutes to a practically normal value. It never fell appreciably thereafter.

To the observer, the return of a normal pink skin color⁶ was one of the most striking effects of the inhalation of carbon dioxid, indicating a return of the normal capillary circulation, a feature of fundamental importance in the recovery from postoperative circulatory depression.

As the patients came off the operating table, they showed invariably the inadequately filled veins which indicate a reduced venous return to the right heart. To combat this condition effectively is, in our opinion, to solve practically the whole problem of the treatment of postoperative circulatory depression. Under inhalation of carbon dioxid, the veins became filled to an extent even exceeding that seen after vigorous physical exertion. We limited the strength of the carbon dioxid administered by this sign, in order not to overload the right heart with blood.

Although vomiting was not entirely absent, it was much less than in untreated patients. The patients were allowed to drink water freely. The inhalations seemed to diminish greatly the usual postanesthetic thirst.

We anticipated from previous experimental observations on animals that one of the benefits to be derived from inhalations of carbon dioxid would be found in the restoration of normal tonus in the stomach and intestine, and thus in the prevention of gas pains and constipation.⁷ While no patient developed gas pains, and all recovered normal bowel movements easily, our total of only seventeen cases treated is not sufficient to warrant a definite conclusion on this point.

BLOOD ALKALI

We turn now to a matter of profound theoretical significance. It is well established that under anesthesia and operation there is frequently a considerable reduction in the alkali of the blood as measured by its carbon dioxid combining power.⁸ But the cause, the nature and the significance of this reduction are not established.

Recent work by Henderson and Haggard⁹ has demonstrated experimentally that a reduction of blood alkali may be induced by two distinct processes: (a) The entrance of acids into the blood may partially neutralize the alkali. This is the acidotic process. Or (b) excessive breathing with blowing off of the carbon dioxid of the blood, reinforced perhaps by diminished carbon dioxid formation in the tissues under anesthesia, leaves the blood abnormally alkaline. In compensation, alkali passes out of the blood, partly perhaps into the urine, but chiefly presumably into the tissues. This is the acapnial process.

To distinguish between these two—superficially similar but fundamentally unlike—conditions of low blood alkali or, as we term it, hypocapnia, experiments on animals have afforded a simple and conclusive test. It consists in the inhalation of 6 or 8 per cent. carbon dioxid. If the condition is of acidotic origin the extreme acidosis, due to the summation of carbonic acid and fixed acids, aggravates the symptoms, and, if pushed, may kill the subjects in half an hour. On the other hand, if the low blood alkali is of acapnial causation, the increase of carbonic acid in the blood induces a compensatory process by which alkali is recalled, presumably from the tissues, into the blood in normal, or even supernormal, amounts. During the period of inhalation of carbon dioxid and high hydrogen ion concentration, recovery of the circulation, respiration and intestinal motility occurs.

With this distinction in mind it was only after very cautious preliminary tests on patients (of which we have omitted an account) that we ventured to push the inhalations with the intensity indicated in the cases reported. As none suffered any ill effect, but all the patients were rapidly restored to a condition of approximate functional normality, their low blood alkali, so far as it occurred, was clearly not of acidotic, but rather of acapnial origin.

To clinch this point we report observations which we were enabled to make at the New Jersey State Hospital for the Insane, Trenton, through the courtesy of Dr. Henry A. Cotton, medical director, and Dr. John W. Draper, of New York, attending surgeon:

CASE 5.—M. F., female, underwent operation for developmental reconstruction, involving the removal of 150 cm. of terminal ileum, about one third of the colon, and a number of mesenteric glands. Ether was administered for 120 minutes. Immediately after the patient was returned to bed, carbon dioxid inhalation was begun and continued for half an hour with the simplified apparatus. Samples of blood were drawn from an arm vein (a) before anesthesia, (b) at the end of operation, and (c) after termination of the carbon dioxid inhalation. They were equilibrated with air containing 5.6 per cent. of carbon dioxid at room temperature, and were analyzed for their carbon dioxid content, that is, the alkali in use.

Analytic results: a = 53; b = 48; c = 58 per cent. carbon dioxid by volume.

CASE 6.—M. A., female, was operated on as in the previous case. Ether was administered for 120 minutes.

Blood samples: $a=56$; $b=42$; $c=57$ per cent. carbon dioxide by volume.

CASE 7.—S. McK., female, had a 5.6 kg. abdominal fibroid tumor and 12 liters of ascitic fluid removed. Ether was administered for fifty-five minutes. The arterial pressure before operation was 154 mm.; after removal of the tumor, 100; after carbon dioxide inhalation, 160.

Blood samples: $a=56$; $b=48$; $c=64$ per cent. carbon dioxide by volume.

CASE 8.—M. M., female, was operated on for appendicitis. Ether was administered for fifty-five minutes.

Blood samples: $a=59$; $b=52$; $c=61$ per cent. carbon dioxide by volume.

THE APPARATUS

The simplified apparatus used in the last series of observations is shown in the accompanying illustration. It involves a tank of carbon dioxide of the best beverage quality, and a reducing valve. From the valve the gas passes to a T-tube, one limb of which leads to a capillary tube 1.8 mm. in diameter and 10 mm. long, and the other limb to a glass tube projecting down into a vessel of water. The latter serves both as a gage and as an escape valve, preventing any excessive pressure on the capillary. Under the maximum pressure possible, not more than 8 liters of gas pass through the capillary, which in turn is connected to the mask by a 5 or 6 mm. rubber tube.

The construction of the mask is simple, but involves the idea of preventing any possibility of accumulation of gas in the mask, with consequent excess administration. It depends on the subject's own breathing to draw the gas in and to mix it with air. These purposes are achieved by delivering the gas through a number of small openings just outside the open end of a short, large tube (from 2 to 3 cm. in diameter) connected with the mask. During expiration, or apnea, the gas merely wastes into the outside air; during inspiration it mixes with the inspired air. The operator controls the administration according to the reactions of the patient. With this apparatus the patient receives approximately one half of the gas which the apparatus measures off per minute. The percentage of carbon dioxide in the inspired air depends on the volume of breathing, and the administration must be controlled accordingly.

These investigations are being actively continued at St. Bartholomew's Hospital for Diseases of the Alimentary Canal, New York, where every facility has been provided for the further development of the carbon dioxide therapy.

CONCLUSIONS

The observations here reported indicate that the inhalation of carbon dioxide, properly diluted with air, is a highly beneficial and, with care, a safe treatment after anesthesia and operation.

The beneficial effects observed are: (a) an augmentation of breathing which rapidly ventilates the anes-

thetic out of the blood; (b) a powerful stimulant effect on the circulation, particularly on the venous return, and a rapid restoration of arterial pressure, without subsequent relapse or unfavorable consequences; (c) marked decrease of postoperative nausea, vomiting and thirst, and (d) a possible restoration of intestinal tonus.

TETANY IN A CASE OF SPRUE*

A. L. BARACH, M.D.

AND

H. A. MURRAY, JR., M.D.

NEW YORK

Early in 1919, Bassett-Smith¹ reported a case of sprue in which tetany developed shortly before the death of the patient. The author stated that his was the first published account of this complication of the disease. As no similar reports have been found in the literature since that time, it was considered that this case might be of interest both on account of its rarity and because of certain significant features bearing on the question of the etiology of tetany.

REPORT OF CASE

History.—R. W. C., an American medical missionary, aged 41, entered the private ward of the Presbyterian Hospital, Sept. 20, 1919, complaining of abdominal pain and diarrhea. As in all previous visits, he was cared for by Dr. David Bo-vaire. The patient had had measles and scarlet fever as a child; dengue in 1909, and bacillary dysentery in 1912. Since 1907, when the patient arrived in the Philippine Islands, small ulcers had been continuously present in his mouth, and he had been

bothered by diarrhea of a greater or less degree. In 1914, his condition became very much aggravated. The tongue became red, swollen and tender, and the small white ulcers along its margin merged. Moderate abdominal tenderness with slight distention accompanied a troublesome diarrhea. The stools were large, white, semifluid and frothy, with an offensive odor. He suffered from hemorrhoids, and fissures appeared in the margin of the anus. In the six months preceding his first entrance to the Presbyterian Hospital, the patient lost 40 pounds.

First Admission.—The patient was admitted, July 24, 1914, and discharged, Aug. 17, 1914. The lips were cyanotic; there were white spots on the tongue; on the buccal mucous membrane were two shallow ulcerations with a narrow zone of inflammation around them. There was a systolic murmur at the apex and the base; the abdomen was tender and tympanitic. The systolic blood pressure was 114; the diastolic, 70. Blood examination revealed: hemoglobin, 88 per cent.; red blood cells, 4,800,000; white blood cells, 9,200; polymorphonuclears, 56 per cent.; lymphocytes, 39 per cent.; eosinophils, 5 per cent. The stool contained no ova or parasites; the Cammidge test was positive; amylase was diminished. The diagnosis was "sprue." Under a regulated dietary regimen of fruit and proteins, the patient

* From the Presbyterian Hospital and the Laboratories of Surgical Research, Columbia University College of Physicians and Surgeons.
1. Bassett-Smith, P. W.: *Lancet* 1: 178 (Feb. 1) 1919.

Simplified apparatus.

improved considerably, and on leaving the hospital went to live in New Jersey, where he seemed to be on the road to recovery. Exercise, however, brought on renewed attacks, and the patient was forced to reenter the hospital in 1916.

Second Admission.—The patient was admitted, March 31, 1916, and discharged, Aug. 5, 1916. He presented about the same symptoms as on his previous admission, with the addition of anemia. Blood examination revealed: hemoglobin, 68 per cent.; red blood cells, 3,600,000; white blood cells, 9,200; polymorphonuclears, 71 per cent.; lymphocytes, 28 per cent.; eosinophils, 1 per cent.; blood Widal test, negative; blood culture, negative. Throat culture revealed no Klebs-Loeffer bacilli. The Wassermann test was negative. The stool was light and frothy; it contained no ova, parasites, blood or pus; trypsin and amylase were markedly diminished; starch granules, striated muscle fibers and fatty acid crystals were seen. Total fat was 39.0; neutral fat, 14.09; fatty acids, 24.91; 60 per cent. or more of the organisms noted were gram positive. A serial test meal was given. The gastric contents after one-half hour showed: free hydrochloric acid, 38; total acid, 62; after one hour: free hydrochloric acid, 41; total acid, 58. A roentgenogram of the stomach revealed a small amount of residue five hours after eating. The diagnosis was "sprue." The patient had occasional attacks of nausea and vomiting. Improvement began with a low fat diet, composed mostly of fruits and lime-water, and continued up to the time he left the hospital.

Third Admission.—The patient returned to the Philippines in October, 1917, where he seemed to do well until January, 1919; at this time his trouble returned with renewed force. He had from two to four light, frothy stools a day, and for the first time was troubled with pain in the upper part of the esophagus. In the late summer, he returned to the United States and reentered the Presbyterian Hospital. He was weak, emaciated and anemic, and his speech was feeble. The tongue was red and raw, with numerous ulcerations, and the buccal mucous membrane was marked by erosions. A faint blow was audible over the mitral ring. Liver dullness was diminished. The abdomen was distended and tender, but there was no mass or rigidity. The spleen was not palpable. The testes were tender.

September 21, blood examination revealed: hemoglobin, 65 per cent.; red blood cells, 3,700,000; white blood cells, 10,100; polymorphonuclears, 69 per cent. There were from one to three foul smelling, light brown and frothy stools a day; they contained no blood or parasites. The Wassermann test was negative. The blood was of Group II. Proctoscopic examination revealed a uniform, curdy, milklike film covering the mucosa, which was dry and shiny; there were no ulcerations; there were internal hemorrhoids.

October 1, 800 c.c. of blood were transfused without reaction.

October 6, the hemoglobin was 70 per cent.; red blood cells, 3,500,000. The patient had occasional attacks of nausea and vomiting.

October 30, he vomited. Examination of the vomitus revealed: free hydrochloric acid, 0; total acid, 24; guaiac test, negative. The sores of the mouth became worse.

October 31, hemoglobin was 63 per cent.; red blood cells, 2,600,000; no abnormalities of the red blood cells were noted.

November 17, in the evening, the patient vomited and complained of generalized abdominal pain. The abdomen was retracted and tense; deep pressure in every part gave pain, which was somewhat relieved later by a poultice.

November 18, 4:30 a. m., a stool of the usual appearance was passed; at 6 a. m., the patient vomited fluid with dark brown particles; at 6:30 a. m. he was in great distress. He said he had been in pain all night both from his abdomen and on account of contractures which had appeared in his extremities. On examination the patient presented the picture of tetany. The upper extremities were extremely spastic, drawn up and flexed at the elbows, flexed and rotated outward at the wrists. The fingers were flexed at the metacarpophalangeal joints, and the interphalangeal joints were extended. The lower extremities were also spastic, with flexion at the knees and extension at the ankles. The retraction and general tenderness of the abdomen, because there

was no fever or localization of the pain, was looked on as an expression of a generalized state of muscular hypertonicity. The patient vomited again. Examination of the vomitus revealed free hydrochloric acid, 0; total acid, 0. Spasms of the extremities disappeared in the late morning. The temperature was between 98 and 99 F.; the pulse, from 70 to 90. The serum calcium was 8 mg. per hundred c.c. (normal, from 9 to 11 mg. per hundred c.c.). An infusion of 400 c.c. of a 0.2 per cent. calcium lactate solution was performed. Thirty minutes later the serum calcium was 8.3 mg. per hundred c.c.

November 19, hemoglobin was 70 per cent.; red blood cells, 3,000,000; polymorphonuclears, 68 per cent. The patient still had abdominal pain, but on account of the normal temperature and low pulse rate, no new abdominal complication was suspected. The serum calcium was 6.5 mg. per hundred c.c. An infusion of 400 c.c. of a 0.2 per cent. solution of calcium lactate was performed. Thirty minutes later the serum calcium was 6.5 mg. per hundred c.c. The patient had frequent involuntary stools during the day. The plasma carbon dioxide capacity was 57.6 per cent. by volume.

November 20, the temperature for the first time rose above normal (102 F.). The pulse was 130. Tetanic contractions reappeared. A transfusion of 400 c.c. of blood was performed. Thirty minutes later the serum calcium was 7.5 mg. per hundred c.c. An infusion of 350 c.c. of a 0.2 per cent. solution of calcium lactate was performed.

November 21, the temperature was 103.4 F.; pulse, 124. There was twitching of the extremities. An infusion of 800 c.c. of a 0.1 per cent. solution of calcium lactate in 0.4 per cent. saline was performed. The patient died.

During the last forty-eight hours, the patient vomited almost constantly except after lavage. The vomitus was first dark green, and later, dark brown. The fever which developed during the last twenty-four hours, by which time the abdomen had relaxed, was considered secondary to the constant vomiting.

The final diagnosis was: tetany; acute dilatation of the stomach, and sprue.

Summary of Postmortem Findings.—There were sprue (clinical); atrophic enteritis; atrophy of the papillae of the tongue, and general purulent peritonitis. The abdomen contained about 300 c.c. of dirty, yellow, purulent fluid. The intestines were matted together with yellowish fibrin and covered with a purulent exudate. The appendix was gangrenous, with rupture; it was hanging over the pelvic brim; in its middle it was necrotic and perforated. There was acute dilatation of the stomach and intestines; the stomach, the duodenum and 2 feet of the jejunum were hugely dilated with fluid and a little gas. The gastric musculature was not thickened; there were cardiac hypertrophy; chronic cardiac valvular disease (aortic valve), and generalized arteriosclerosis. The bone marrow was hypertrophic. The parathyroids were normal.

COMMENT

A diminished concentration of calcium in the blood has been shown to produce tetany, and in the case under discussion, the lack of this element was demonstrated by analysis of the blood. As bearing on the question of the cause of the disturbance of calcium metabolism in this particular individual, the following points are emphasized:

1. According to von Noorden, calcium is absorbed in the upper part of the small intestine, combined with phosphoric and carbonic acids, but more especially with fatty acids in the form of soaps. Sprue patients, however, and many stool examinations proved it in this case, cannot readily digest fats. Is it not conceivable, then, that calcium was carried on with the fats, and that its absorption through the diseased intestinal mucosa was insufficient to maintain the proper balance? This is mentioned as a possible predisposing factor.

Calcium is mostly excreted into the large bowel; and in the present instance, owing to the prolonged intes-

tinal irritation lasting over six or more years, the excretory rate of the substance by this outlet may have been abnormally increased. Such abnormal elimination would have tended to disturb still further the calcium equilibrium.

2. Clinically, tetany is occasionally associated with gastric dilatation, usually following pyloric obstruction and accompanied by considerable vomiting. We have produced pedal spasms in dogs by simply closing the pylorus with a ligature, and have found, as did McCann,² that an increased concentration of carbon dioxid bound as bicarbonate in the plasma, and a gradual diminution and final loss of free or combined hydrochloric acid in the gastric contents, resulted from this procedure. Gastric tetany is not known to be associated with a diminished calcium concentration in the blood, although calcium therapy relieves it.³ Comparison with this case reveals certain similarities and decided differences as well. There was some vomiting, and at necropsy the stomach as well as the duodenum was found hugely dilated, but with no pyloric obstruction. A specimen of vomitus examined shortly after the onset of tetany showed that there was no acid present; however, in the presence of a patent pylorus this may well have been due to duodenal regurgitation. A Van Slyke carbon dioxid determination revealed no alkalosis (57.6 c.c.). Furthermore, there was an actual decrease in the calcium concentration of the serum unrelieved by calcium lactate infusions. These findings are opposed to the classification of this case as one of simple so-called "gastric tetany," even though the factors involved may have had some causal influences.

3. Tetany occurs as a rare complication of acute infectious diseases, but in this instance it seems far fetched to attribute any direct etiologic significance to the appendicitis and general peritonitis found at necropsy.

4. Calcium infusions can usually be counted on to abolish the seizures of tetany, but in this case there was no abatement, and the failure was mirrored in the blood analyses. It was a great surprise to find that injections of as much as 400 c.c. of a 0.2 per cent solution of calcium lactate, which theoretically should increase calcium to the extent of about 5 mg. per hundred c.c., had no such effect. Within thirty minutes after both infusions, the quantity of the calcium introduced had left the blood flowing through the peripheral circulation. Was the calcium excreted in that short period into the intestine, was the condition of the blood colloids such that the calcium present existed in saturated solution and any additional calcium was immediately precipitated, or was calcium immediately claimed by lime-starved tissue cells? That this is not the case in parathyroid tetany is shown by the following analyses, made at the same time as the foregoing determinations:

In a dog in acute tetany, the serum calcium was 5.1 mg. per hundred. Infusion of 40 c.c. of 1 per cent. calcium chlorid solution was followed by complete cessation of symptoms. The serum calcium, thirty minutes later, was 9 mg. per hundred.

That the condition of the blood was an important factor is suggested by the rise in calcium following the transfusion of normal blood. We consider some of these points suggestive, but not conclusive enough to form any hypothesis for explaining the course of events which led up to the state of tetany.

AGREEMENT IN RESULTS OF THE WASSERMANN REACTION

A STUDY OF TESTS PERFORMED BY TWO LABORATORIES IN THREE THOUSAND SUCCESSIVE HOSPITAL ADMISSIONS *

HARRY C. SOLOMON, M.D.

Member of the Massachusetts State Psychiatric Institute
BOSTON

It has been the custom at the Psychopathic Department of the Boston State Hospital, for the past few years, to have the blood of each patient examined by two independent laboratories. This was done primarily for the safeguarding of the patient against erroneous conclusions based on one test; and, secondarily, in order to obtain information which would be valuable to ourselves in estimating the results of the laboratories; that is, to put us in a position in which we would be able to interpret the findings more correctly. The two laboratories selected for this purpose were the laboratory of the Massachusetts Department of Health and the laboratory of the Boston City Department of Health. Dr. Hinton and Dr. Castleman, of the respective laboratories, were most cooperative and desirous of having this work carried out, both for our own information and for what service it would be to them in estimating their own work. The spirit of these men cannot be too highly commended, and the results that are presented herewith are indicative that not only in this respect, but in all others, they have attempted to bring a high standard into their laboratories.

A Wassermann test made on each patient admitted to the hospital is, and has been, a routine since the opening of the hospital. During the time that the tests were made in the two laboratories, it was customary to bleed the patient into two test-tubes, one tube being sent to the city laboratory, the other to the state laboratory, conditions thus being as nearly similar as possible. To date, 3,000 patients have had their blood tested in this way. In some cases the test was repeated several times, especially in those cases in which there was a difference in the report.

Without going into any details of the technic used by these two laboratories,¹ it may briefly be stated that Laboratory A uses three cholesterinized antigens of different sensitivities to check each positive reaction; Laboratory B, in addition to the cholesterinized antigen, employs an acetone insoluble antigen.

Whenever possible, those cases in which the reports were not the same from the two laboratories were retested, in an endeavor to get a report free from technical error. Unfortunately, the patients, as a rule, stayed only a few days at the hospital, and it was not possible to carry this out as far as was desired in many instances. However, in a number we were able to get a uniformity of results after the first test, rather indicating that the result of the first test might have been due to some technical error; and this, as a possible explanation, is further borne out by the fact that some cases were tested many times by one laboratory, with the result that occasionally a case giving consistently positive results for ten, fifteen or more tests, would suddenly give a negative reaction, to be followed again

* From the Massachusetts State Psychiatric Institute.

1. The designations Laboratory A and Laboratory B are used throughout as this is not intended as an attempt to show relative merits of the two laboratories, but rather to indicate the value of the Wassermann test.

2. McCann, W. S.: *J. Biol. Chem.* **35**: 553 (Sept. 18) 1918.

3. Kinneutt, F. P.: *Am. J. M. Sc.* **138**: 1, 1909.

by a series of positive tests. It is possible, of course, that this may have been due at times to some change in the patient's serum, a condition which is not so very likely, and which, at any rate, is not explicable. Of especial interest in this work is a group of tests which we have made on children suspected of congenital syphilis, and who all fall into a class of poorly nourished and mentally retarded children. In this group, we found a series of reactions differing from one another somewhat as follows: doubtful, negative, positive, negative. We have never noticed this result in adults or in apparently healthy children. In these cases we have felt that the Wassermann reaction has not been of especial value in determining our diagnosis of congenital syphilis.

The tests are reported a little differently in the two laboratories. Laboratory A reports "positive, doubtful and negative," the positive test representing what is sometimes spoken of as a ++++ reaction, which is a strongly positive test in the three antigens used.

VARIATIONS IN THREE THOUSAND CASES

	No.	Per Cent.
Total number of variations, including those reported positive, moderately positive, or doubtful by one laboratory and negative by the other	197	6.56
Cases reported positive or doubtful by Laboratory A and negative by Laboratory B	70	2.33
Cases reported positive, moderately positive, or doubtful by Laboratory B and negative by Laboratory A ..	127	4.23
Cases reported moderately positive or doubtful by either laboratory and negative by the other laboratory	77	
Cases reported straight positive by either laboratory and negative by the other laboratory	120	4.0
Cases reported straight positive by Laboratory A and negative by Laboratory B	42	1.4
Cases reported straight positive by Laboratory B and negative by Laboratory A	78	2.6
Cases in variation group known to be syphilitic	35	
Cases in variation group known to be syphilitic reported positive by Laboratory A and negative by Laboratory B	20	
Cases in variation group known to be syphilitic reported positive by Laboratory B and negative by Laboratory A ..	15	
Possible false positives (including positive and doubtful) from Laboratory A (70-20)	50	1.66
Possible false positives (including positive, moderately positive, and doubtful) from Laboratory B (127-15) ..	112	3.4
Considering only the 42 straight positives from Laboratory A and subtracting the 20 known to be syphilitic (these happened to give straight positive reactions) the possible false positives are	22	0.73
Considering only the 78 straight positives from Laboratory B and subtracting the number of these known to be syphilitic (5), the possible false positives are	73	2.43

The doubtful reaction is reported in those cases in which one or two of the antigens gave a strong inhibition of hemolysis, with complete or nearly complete hemolysis in the other one or two antigens. Laboratory B reports "positive" for the strongly positive reactions; "moderately positive" for the reactions not so markedly positive, and "doubtful" when there is not a complete uniformity in the reactions of the different antigens. In both laboratories, "negative" represents the condition interpreted as the absence of the test for syphilis.

The accompanying table summarizes the results obtained in these 3,000 cases. (Approximately 15 per cent. of the cases tested positive.)

It seems only fair to state that a moderately positive or doubtful Wassermann reaction is not sufficient evidence on which to base a diagnosis of syphilis, unless backed by other strong points. It is always advised that in such a case the test be repeated until either a strongly positive or a definitely negative reaction is established. Hence, in considering the possibilities of going wrong in accepting the reactions of one laboratory, one would consider only the cases that are reported as straight positives. As the table indi-

cates, the percentage variations between the two laboratories, considering the straight positives, is only 4, a percentage which we consider exceedingly low, and justifying the technic of these laboratories to a high degree.

If the possibility of making an erroneous diagnosis of syphilis, based on a positive reaction from but one laboratory, is considered, we see that this is reduced greatly, in that the percentage from the one laboratory is 1.4, and from the other, 2.6. This is stated on the assumption that when one laboratory gives a negative reaction and the other a positive, the positive does not represent syphilis. This is obviously not a correct hypothesis, as we have to deal with cases which are undoubtedly syphilis, but which give negative reactions in one laboratory, due either to the weakness of the antigen, or to a technical error. We therefore went over the cases in which this discrepancy occurred, from the clinical standpoint, and considered only those cases in which very definite evidences of syphilis were obtained. This included cases in which the history was absolute, such as patients that had been known to have syphilis and had given a positive Wassermann reaction in the past and had been under treatment, or cases of syphilis of the central nervous system, in which the spinal fluid findings were positive. Many cases highly suggestive of syphilis, from the fact either that the patients were prostitutes or that they had had symptoms on which one would practically be justified in making a diagnosis of syphilis, were considered as not syphilitic, in order not to prejudice the conclusions in favor of the laboratory. Deducting the cases, then, that were undoubtedly syphilitic, we find that of the 3,000 cases tested, Laboratory A returned twenty-two positive reactions which were reported negative in the same cases by Laboratory B, and which did not give definite evidence of syphilis. This would make a possible "false positive" report (i. e., a positive reaction, due to an error in the performance of the test, on a nonsyphilitic serum) in only 0.73 per cent. From Laboratory B this percentage² was 2.43. These low percentages are undoubtedly higher than the facts justify, as there can be no doubt that some of these cases were syphilitic. However, if we accept these figures as the worst possible, they are still such that we can place a great deal of confidence in the reports of the laboratories. This study shows that it is possible to obtain "false negative" or "false positive" reactions. It should be emphasized strongly that these figures as given represent a discrepancy between the two laboratories on the first test. In the majority of cases, a uniformity of report was obtained on repetition.

While these figures are exceedingly low, and therefore very satisfactory, it is true that no matter how small the percentage of error may be, if it affects any given individual it is a 100 per cent. error for that individual, and therefore it is the duty of the clinician to protect him as far as is possible. This can be accomplished in a number of ways. Several repetitions of the test giving uniform results is very good evidence that the result as reported is correct. Secondly, having the blood tested by two laboratories simultaneously affords a good check. If there is a discrepancy, that is evidence that one or the other test may be an error, and a repetition of the test is indi-

2. The blood frequently did not reach Laboratory B for three or four days after being taken. There is evidence that blood which has stood for some time may give positive results in nonsyphilitic cases because of contamination.

cated. It should be emphasized that a knowledge of the laboratory and its standards, technic and method of reporting is more important in obtaining the information desired than the reports from a number of laboratories which may not be careful or accurate. In other words, it is the clinician's duty to know the possibility of error in the laboratory that he is using. It is much better to have a test repeated several times in a laboratory to whose technic one is accustomed than to have a single test made in several laboratories, which will only lead to confusion, especially when one remembers that the sensitivity of the antigens plays a considerable rôle.

It is true that occasionally on certain days things do not go entirely well in a laboratory, and it is found that one particular day may give a high percentage of positives. This affords a means of checking up the results, and is commonly used by the laboratory chiefs. Thus, it is usual to run known positive and known negative serums for this purpose. It is possible for the clinician to use a similar check on the laboratory. In hospital practice, in which a great number of tests are made each day, it is possible to draw a conclusion as to whether too high or too low a percentage of positives is received. For example, on a certain day, if we find that a number of cases in which there is no reason to suspect syphilis are reported as giving positive Wassermann reactions, we may be suspicious that something may have gone wrong in the laboratory. On the other hand, if our known syphilitics give negative reactions, this is also highly suggestive. Thus, the patient may be amply protected against incorrect reports, and the value of the Wassermann test greatly enhanced by the clinician himself.

A comparison of the results as shown in this study with results expected from other laboratory tests seems to us to be extremely satisfactory. The results would seem to be as good as one would expect from a Widal reaction, a Schick test, a diphtheria smear, or a single examination of the urine in a case in which nephritis is suspected. It is only fair to admit that we were somewhat surprised to find how well the tests of these two laboratories checked. Until we really added up the figures, our impression was that there were very many more variations. This was undoubtedly the result of the individual equation. Each instance in which there was a discrepancy stood out strongly and clearly, whereas those that agreed were passed over without any consideration whatsoever.

SUMMARY

The blood serums of 3,000 patients were subjected to the Wassermann tests by two independent laboratories. An analysis of the results showed that there was a complete uniformity in the findings of the two laboratories in 93.44 per cent. The 6.56 per cent. variation included cases reported as doubtful. Considering only the variation of cases reported positive by one laboratory and negative by the other, the percentage variation was 4. This was 1.4 per cent. positive in one laboratory and 2.6 per cent. positive by the other laboratory. Some of the cases reported positive by one laboratory and negative by the other were known to be syphilitic, so that the negative reaction was the incorrect one. Considering, then, the cases that either laboratory may have reported as positive in nonsyphilitic cases, the percentage was 3.16. This is probably a higher percentage for false posi-

tives than actually occurred, as some of these cases were presumably syphilitic. This percentage variation is based on only one test. Repetitions resulted in a uniformity of findings in the majority of cases. This is considered a good testimonial for the accuracy of the tests as performed in these two laboratories.

DUODENAL PERFORATION (FISTULA) TREATED BY DUODENAL (JEJUNAL) ALIMENTATION

ANOTHER CASE

MAX EINHORN, M.D.

Professor of Medicine, New York Post-Graduate Medical School;
Visiting Physician, Lenox Hill Hospital
NEW YORK

About a year ago I reported a case of duodenal perforation successfully treated by jejunal alimentation.¹ As these cases are rare and of difficult management I take the liberty of reporting another case with duodenal fistula which I recently had under observation in conjunction with Dr. Willy Meyer.

REPORT OF CASE

History.—A. P. P., man, aged 50, born in the United States, seen, May 10, 1919, was first seized twenty years before with an attack of pain and gas in the epigastrium, which lasted several hours. Eight years later, he had three attacks in a period of three months. Five years later, the attacks came on more frequently and then disappeared until the past six or seven years, when they came on two or three times a year. The attacks were sudden, lasted at the utmost twenty-four hours, disappeared, and would not recur for a long period. During the attacks there was severe pain in the epigastrium, radiating across both sides of the abdomen. There had been no vomiting, but continuous belching of gas. The patient said that when he walked 2 or 3 miles the attack would disappear more readily than otherwise. The pain had no relation to food. The bowels were usually constipated. There was never any jaundice. During the attack the patient would lose 6 or 7 pounds, which, however, he would quickly regain. The chief complaints at the time of the examination were distress in the epigastrium, and constipation.

Physical Examination.—The only positive relevant finding was epigastric pain on deep pressure. The gastric contents were positive for hydrochloric acid; hydrochloric acid, 24; acidity, 54; blood, negative; there were numerous starch granules, a few leukocytes, bile, mucus and epithelial cells. The duodenal contents were greenish yellow and very turbid; alkalinity, 30; amylopsin, 5; steapsin, 2; trypsin, 4; there were cholesterol crystals, calcium bilirubin crystals and bacteria. Bacteriologic examination yielded colon bacillus and staphylococcus. The duodenal bucket revealed bile stain, 53-63; no blood stain. Contents from duodenal bucket: amylopsin, 0; steapsin, 0; trypsin, 0; hydrochloric acid \pm . The white blood count was 9,800; polymorphonuclears, 61 per cent.; lymphocytes, 39 per cent.; hemoglobin, 80 per cent. Roentgen examination was negative with regard to the gastro-intestinal tract and the gallbladder. The Wassermann test was negative. In the urine, albumin varied from negative to a trace; there were a few red blood cells and a few white blood cells; sugar was negative. The systolic blood pressure was 115; diastolic, 74. The feces was negative for blood; mucus was present; there were no ova.

Based on the findings of the duodenal contents, very turbid bile in the fasting condition, and the history, a diagnosis of cholecystitis with probable gallstones was made, and an operation advised.

1. Einhorn, Max: A Case of Duodenal Perforation Successfully Treated by Duodenal (Jejunal) Alimentation, *Med. Rec.* 94: 927 (Nov. 30) 1918.

Operation and Result.—Dr. Willy Meyer, May 26, performed a cholecystectomy. The gallbladder was found filled with stones. The pathologic diagnosis was chronic catarrhal cholecystitis. The patient was discharged from the hospital, July 12. Three weeks after the operation, the last tampon was removed. After that, bubbles of air came from the upper angle of the wound. Then a persistent discharge developed from this part of the wound. Frequently a great many bubbles of gas would come up from the same source and annoy the patient greatly. He was first seen by me with this discharge, October 11. The discharge was examined and found to contain food, was alkaline, and looked rather grayish.

EXAMINATIONS OF DUODENAL CONTENTS AS OBTAINED FROM
THE FISTULA AND THROUGH THE DUODENAL TUBE

Date	Reaction	Discharge from the Fistula			Comment
		Amylopsin	Steapsin	Trypsin	
10/11/19	Alkaline	2	0	0	Food present; many pus corpuscles; few red blood cells
10/15/19	Alkaline	—	—	—	Direct smear: white blood cells; milk; red blood cells; mucus
10/26/19	Alkaline	—	—	—	No food; pus corpuscles; few red blood cells
Date	Reaction	Duodenal Contents Obtained Through the Tube			Comment
		Amylopsin	Steapsin	Trypsin	
10/21/19	Alkaline	5	2	1	Yellow; slightly turbid; mucus; pus corpuscles
10/24/19	25	9	1	3	Golden-yellow; mucus
10/25/19	20	9	1	3	Yellow, bile-stained cells; white blood cells; goblet cells
10/25/19	25	6	1	2	Here the duodenal contents were yellow, brown and turbid

The accompanying table shows the result of examination of the fistula discharge as contrasted with the duodenal contents proper obtained through the tube.

The discharge being slightly alkaline, containing food, and hardly any traces of bile, the diagnosis of a duodenal fistula in the ascending portion of the duodenum, probably not very far from the pylorus, was made. The patient was then given duodenal (jejunal) feeding. A duodenal tube (44 inches long) was inserted, October 15. Duodenal feeding was started, October 17.

October 22, a roentgen examination was made by William H. Stewart. The tube, inserted through the fistula, entered the duodenum and ran parallel with the duodenal tube.

October 27, the tube, being clogged, was removed, cleaned and reinserted. It was left in place until November 19; another tube was introduced, November 23.

December 4, the wound closed by itself; the tube was removed.

December 12, the patient was discharged from the hospital.

December 22, I saw the patient. The wound had healed perfectly, and the patient had gained in weight and strength.

COMMENT

The diagnosis of a duodenal fistula situated between the pylorus and the papilla of Vater was established by the character of material oozing from the fistula. It was of alkaline reaction and contained food particles and usually no bile. As the patient had enough acid in his stomach the fistula must have come from the duodenum. The frequent absence of bile in it demonstrated that the opening must be situated above the papilla of Vater. This conclusion appears to find corroboration in the roentgen-ray examination and also in the clinical syndrome of the case.

The roentgen ray shows the catheter inserted into the fistula, meeting the duodenal tube a short distance from the pylorus.

Among the symptoms the patient presented from the fistula, the intense inflammation of the skin around the

duodenal fistula usually encountered was missing here, the skin preserving its natural color. This must be explained by the fact that the secretion did not contain pancreatic juice, as is in fact seen from the examinations of the fistulous material given in the table. The lack of pancreatic juice likewise speaks for the location of the fistula above the papilla of Vater.

The treatment consisted of atropin in conjunction with the jejunal alimentation. The patient first lost considerable weight (20 pounds). After three weeks of jejunal alimentation, the tube was pulled up to some extent so that the capsule end was now situated in the duodenum proper. We now had real duodenal alimentation, which agreed with the patient much better, as he did not lose any more in weight.

A short while after the jejunal alimentation had been begun there was no food found in the secretion from the fistula, although some pus corpuscles and a few red blood corpuscles were always encountered. A little while later, December 4, the opening closed up by itself and has remained closed ever since. The patient is now enjoying perfect health. He eats and drinks anything he chooses, without any discomfort. He has regained his lost weight, and there is no trace of the fistula left, excepting the visible scar on the abdomen.

The healing of the fistula by duodenal alimentation, in the case described and in the one reported a year ago, shows that we have in the duodenal tube, and the method of feeding through it, an important aid to overcome this very tedious and what was formerly thought to be an almost intractable condition.

20 East Sixty-Third Street.

GUMMA OF THE BREAST

REPORT OF A PROBABLE CASE

LOYD THOMPSON, M.D.

HOT SPRINGS, ARK.

The paucity of references, particularly by American writers, to the subject of syphilis of the breast makes this report and a review of the subject at this time desirable.

REPORT OF CASE

History.—Mrs. W. E. S., aged 33, housewife, came to me, Oct. 27, 1919, complaining of "nervousness" at times, pains in the arms and neck, frequent headache and a lump in the breast. An older sister was operated on for cancer at 36. The mother was living and well at 65. The father died following an injury. Five brothers and sisters were living and well. The patient had had appendicitis nine or ten years before, followed by several attacks. After the lapse of eighteen months, the appendix was removed. She had had measles as a child. She had been married twelve years and had had a miscarriage at seven months during the first year, and a second miscarriage at two months during the second year. I treated the husband for syphilis during the early spring of 1917. He had suffered from this disease for three years before marriage, but was assured by his family physician that he was cured. The patient never showed any outward manifestations of the disease, had enjoyed quite good health all her married life, and at the time I treated her husband, her blood Wassermann reaction was negative. About January, 1918, she began to notice pains and nervous twitchings in the neck, arms and legs. These were never severe. The lump in the breast was noticed in November, 1918, at which time it was about the size of a walnut. It gradually became larger, and during the summer of 1919 she was examined by a surgeon and had a Wassermann test made. This was reported as weakly positive. A short time

before coming to me she was examined by another physician, at which time her blood Wassermann reaction was strongly positive, and in spite of this he advised her to have an operation at once. This she refused, and came to me for treatment.

Examination.—The external genitals were negative. The superficial lymphatic glands were not palpable. The skin and mucous membranes were negative. An examination of the bones revealed a slightly tender spot on the sternum. The heart, lungs and abdomen were negative. The systolic blood pressure was 110; diastolic, 80. The eyegrounds were negative. The pupils reacted to light and accommodation. The left knee jerk was quite sluggish; otherwise the neurologic examination was negative. An examination of the left breast revealed a tumor of horseshoe shape, about 4 inches long and from 1 to 1½ inches in diameter, in the lower left quadrant of the breast. This was not tender, and the axillary glands on the left side were not enlarged. The blood Wassermann test by the classical method, with cholesterinized antigen, was +++; in the ice-box and by the Thompson modification, ++++. A diagnosis of gumma of the breast was made and the patient placed on treatment.

Treatment and Course.—Mercuric benzoate was administered intramuscularly in doses of 0.02 gm. daily. Potassium iodid was given by mouth, 10 drops three times a day, increasing 5 drops daily until 100 drops three times a day were reached. Neo-arsphenamin in 0.6 gm. doses was administered at weekly intervals for six weeks. At the end of this time, Dec. 8, 1919, the tumor had decreased in size until it was about one fourth of its original dimensions, when the patient was forced to leave for her home, but promised to return for further treatment if the tumor began to increase in size. About six weeks after leaving Hot Springs the patient began taking "mixed treatment," which was continued more or less regularly till Feb. 26, 1920, when I again saw her during a visit to her home city. At this time the tumor had become considerably smaller and had divided into two parts, one being about the size of a walnut and the other one about half that size.

In view of the history of syphilis in the husband, the two miscarriages, the positive Wassermann test and the result of the therapy, there seems to be no doubt that this case was one of gumma of the breast.

HISTORICAL

Most writers on the subject of breast syphilis state that Sauvages,¹ in 1768, was the first to recognize this condition. However, Astruc,² as early as 1736, speaks of cancer of the breast as one of the symptoms of syphilis peculiar to women, but does not mention any specific instances. Sauvages' case undoubtedly was one of gumma of the breast. An unmarried woman of 30, who had contracted syphilis ten years before, presented a hard and knobby tumor in each breast, the size of a hen's egg, both of which were painful. There were also present small ulcerations in the mouth and the vagina. All symptoms of lesions cleared up in six weeks under mercury, and never recurred.

The leading syphilographers who followed Astruc in the latter part of the eighteenth and the early part of the nineteenth centuries, notably Hunter,³ Bell,⁴ and Swediaur,⁵ do not mention syphilis of the breast; but about the middle of the nineteenth century gummas of the mammae began to be recognized, and cases were reported by Yvaren,⁶ Verneuil,⁷ Richet,⁸ Velpeau,⁹

Lancereaux¹⁰ and others. The latter author, in his *Traité de la syphilis*, published in 1867, gives a very good description of the condition and mentions five or six cases which had been reported. Since that time, reports of less than forty cases have appeared, and these mainly in the French and German literature.

PATHOLOGY

The only description of the pathology of syphilis of the breast which I have been able to find is that of Reinecke,¹¹ who described a case of syphilitic mastitis. The patient was a woman of 37, who died from uremic coma. The kidneys and spleen were extensively amyloid, and the liver the site of gummas and deep scars. The upper half of the breast was very hard, the tissue on the cut surface dry, while numerous red or yellowish-red, circumscribed foci, the size of a pinhead or larger, projected above the cut surface. These red, firm nodules were found to be due to proliferation of the interlobular and intralobular connective tissue, with degeneration and destruction of the glandular cells whose place was being taken up by connective tissue. The vessels, especially the arteries, were markedly thickened. While this description is not that of gumma, in the strictest sense, the nodules may be considered as small gummas, and there is no reason to believe that larger gummas of the breast would show any essentially different histopathology than similar lesions of other regions.

CLINICAL HISTORY

While gummas of the breast are more common in women (about three fourths of the reported cases occurring in that sex), they are sometimes seen in men. One or both breasts may be affected; and the tumors may be single or multiple, varying in size from a pea to an orange, or larger. They may be subcutaneous or intraparenchymatous. They may occur in any portion of the breast, and usually appear as hard, well circumscribed, movable tumors, which slowly increase in size. As a rule there is no pain, but in a few cases this has been a rather marked symptom. This was true in one of Bissell's¹² cases, in which the pain was sharp and always occurred at night. Sometimes, while there is no pain, the tumor is exceedingly tender on pressure. Usually there is no involvement of the lymphatic glands of the axilla, but this has been reported in some cases.

If untreated, these tumors go on to softening ulceration and sloughing. The ulcerations present the typical punched-out appearance of ulcerating gummas of other regions, with more or less infiltration of the borders. When sloughing occurs the lesion is most foul smelling and filled with a grumous, brownish fluid. A most remarkable case of this kind was reported by Bryant,¹³ in which the entire breast sloughed out and left a clear, granulating surface. Actual gangrene also has been noted, as in Robinson's¹⁴ case.

Usually the tumors are not adherent to the overlying skin, and they are freely movable. As a rule, also, the nipples are not retracted, but this does sometimes occur, as in the case of Gay.¹⁵

Gummas of the breast may also affect congenital syphilitics, and cases have been reported by Gay,¹⁵ Gromo,¹⁶ Neumann¹⁷ and others.

The breast may also be the seat of gummas which have extended from gummatous lesions of the skin over the breast, or from gummatous lesions of the underlying ribs.

DIAGNOSIS

Any tumor of the breast should be looked on with suspicion, and careful anamnesis and examination for other evidences of syphilis, including the Wassermann reaction, should be made.

In women, the history is not of so much importance, as quite frequently women are not aware of a syphilitic infection, although a history of miscarriage would be at least suggestive. Too much reliance also is not to be placed on a negative history in men, as for various reasons the history may be given incorrectly.

Of course, the differential diagnosis of any breast tumor can be made by microscopic examination of a section; but it is unwise to perform a biopsy for such an examination unless preparation is made to perform at the same time a radical operation for carcinoma if the tumor is found to be such.

Gumma of the breast is to be differentiated from chancre, abscess, benign tumor, carcinoma, sarcoma, tuberculosis, actinomycosis and sporotrichosis.

Gumma of the breast sometimes markedly resembles chancre and has been mistaken for this condition. However, as a rule, spirochetes can be demonstrated in chancre, while they are very hard to find in gumma, and the axillary lymph glands are more frequently enlarged. If the chancre is seen early, the Wassermann reaction will be negative, but later will become positive, while with gumma it may or may not be positive.

Abscess of the breast will present more pain than gumma, will fluctuate, and on aspiration, pus will be found.

Benign tumors may be most difficult of differentiation, as they never cause enlargement of the axillary lymph glands. The Wassermann reaction, however, is negative.

Carcinoma of the breast, as a rule, occurs later in life than does gumma. The process of ulceration is slower, the involvement of axillary glands more frequent and occurs earlier, while carcinoma is usually more painful than gumma.

Sarcoma of the breast is very rare; but the differentiation from gumma may be most difficult, and recourse to laboratory aid may be necessary.

In tuberculosis of the breast, the axillary glands are virtually always enlarged. Sinuses and fistulas are usually formed by the gradual extension of the process to the surface, while an examination of the discharge, as a rule, will show tubercle bacilli.

Actinomycosis of the breast is rare, and is to be differentiated from gumma by the finding of ray-fungus in the pus of the discharge.

Sporotrichosis of the breast is more rare, and its differentiation can be accomplished by the finding of the causative organisms.

Finally, in the diagnosis of gumma of the breast, it may be necessary to apply the therapeutic test. This is particularly true in the presence of a positive history or other clinical evidence of syphilis, or a positive Wassermann test.

PROGNOSIS

The prognosis of gumma of the breast in the main may be said to be good, though the prognosis for complete disappearance of the lesions depends on the recognition of the condition before ulceration has taken place. If the latter has occurred, while the lesions may, and usually do, heal under medication for syphilis there may be more or less scarring and, if the destruction of tissue has been great, considerable deformity.

TREATMENT

The treatment of gumma of the breast is the treatment of syphilis. It includes arsphenamin, mercury and iodids in some form or other. Sodium iodid intravenously in doses from 1 to 2 gm. and larger is to be highly recommended when large doses of potassium iodid by mouth are not well borne. In ulcerating lesions, local application of some powder, such as calomel and bismuth, equal parts, boric acid, acetanilid and calomel, equal parts, or aristol (thymol iodid) is highly beneficial.

It goes without saying that general hygienic measures should be instituted in gumma of the breast as in other types of syphilis.

LARYNGEAL CRISIS WITH AN UNUSUAL COMPLICATION

REPORT OF CASE

LEWIS T. GREGORY, M.D.

EVANSTON, ILL.

History.—Mrs. G. (27804), American, white, aged 39, widow, laundress, admitted as a suspicious case of tuberculous laryngitis to the Isolation Department of the Evanston Hospital, on the service of Dr. S. V. Balderston, complained of sudden attacks of difficulty in breathing: "tightness" in chest; hacking cough and hoarseness. She had not been well since an attack of influenza in the preceding fall. The present trouble dated back only about one month, when the patient developed a "cold" in the head, but paid little attention to it, as she was bothered with chronic catarrh. Four days before admission, the patient had a sudden attack of difficulty in breathing, which passed off in a few minutes. These paroxysms became more frequent and of greater severity. She had eight attacks during the first forty-eight hours after admission to the hospital, and about an equal number at home before coming to the hospital. She was unable to describe the "tightness" in her chest, but stated that the sensation was noticed only during the paroxysm. The cough was a more or less continuous hacking cough, and the hoarseness had become progressively worse until the patient was scarcely able to speak above a whisper. The patient had had the illnesses of childhood; "chronic rheumatism," chiefly in the legs, and worse at night; an abdominal disturbance leading to the removal of an ovarian cyst and the appendix four years before; sore throat several years before, which resisted treatment for a long time, and influenza last fall. The family and menstrual histories were negative. The patient had never been pregnant, and denied venereal infection. Her appetite was good, she slept fairly well, and there was no gastro-intestinal, pulmonary, cardiovascular or genito-urinary trouble not already mentioned.

Physical Examination.—The patient was well developed; she was somewhat hoarse, and occasionally gave a dry hacking cough. The temperature was 98 F., the pulse rate 88, and respiration 24. There was a large perforation of the nasal septum. The patient stated that she had had several operations on the nose for catarrh. Very slight symmetrical

16. Gromo: Contribution à l'étude des goîmmes du sein. Paris, 1878.

17. Neumann: Ueber die syphilitische Erkrankung der Brustdrüse. Allg. Wien. med. Ztg. 34: 593, 1889.

edema of the vocal cords was found. There were many small atrophic scars all over the chest and back. The patient said that these came from "pimples" that she had had several years previously. There were marked tenderness and slight roughening over the tibia of both legs. Examination of the throat, mouth, neck, lungs, heart and abdomen, and of the urine and blood yielded negative results. The neurologic examination was negative except for a slightly sluggish reaction of the pupil to light.

Treatment and Course.—Syphilis was suspected, and a Wassermann test was ordered. Before the report from the laboratory was received from this, a report of the nose and throat cultures (taken as a routine on admission) was positive for diphtheria. Ten thousand units of antitoxin were given.

As mentioned in the foregoing, during the first forty-eight hours after admission she had eight paroxysms of difficult breathing. I saw her in three of these. She would suddenly become very hoarse, and within a few seconds would have air hunger, which became progressively severe, until respiration was almost impossible, and the lips and face became markedly cyanosed. Before a hypodermic injection of atropin could be administered, the paroxysm was over. The average duration of these paroxysms was about three minutes. Between attacks she felt perfectly comfortable except for the slight cough and hoarseness.

On the third day, the Wassermann report came back ++++ with fresh and inactivated serum and with two antigens. A diagnosis of syphilitic laryngeal crisis (laryngeal stroke of Charcot) was made, and antisyphilitic treatment was instituted. Neo-arsphenamin, 0.45 gm., was given intravenously, and daily mercury rubs were started. After the first injection, the hoarseness started to clear up, and she had no further paroxysms.

It was necessary to keep her in quarantine for twenty-seven days before diphtheria bacilli had disappeared from the throat and nose.

To date she has kept up the weekly intravenous injection and daily rub, and so far has had no return of any of the symptoms, and the tenderness over the tibia and the nightly pains in the legs have entirely disappeared.

SYPHILITIC LARYNGEAL LESIONS

Conner,¹ in 1903, reviewed the literature of syphilis of the larynx, and found that 128 cases had been reported. None of these, however, appear to be of a tabetic type, but were syphilitic lesions localized in the larynx proper.

Weinstein,² in 1916, reported a case more like the one reported above. The patient lost his voice, and a week passed before a diagnosis was made. Neo-arsphenamin was administered intravenously, and within five hours his power of speech had returned.

Kyle,³ in 1918, gave a summary of the various syphilitic laryngeal lesions. He distinguished: (1) mucous patch; (2) thickening of the vocal cords; (3) paresis, variable from week to week; (4) gumma; (5) ulceration; (6) cicatricial changes, and (7) invasion of contiguous parts. He also stated that a primary syphilitic laryngeal lesion has not been reported, and that gumma is the most frequent type.

COMMENT

The case reported was apparently a syphilitic laryngeal paresis, corresponding to a gastric crisis, so frequently seen. It might have been an unusual type of diphtheritic paresis, but this is not likely, as there was no history of any diphtheritic process and no local evidence of diphtheria in an active form. Furthermore,

it was a paresis, transient in type, and not a paralysis, as usually seen following diphtheria. Finally, the Wassermann reaction was strongly positive with other evidence of syphilis as seen in the sluggish pupil, perforated septum, scars on the back and chest, and painful and roughened tibia, with a history of chronic sore throat and nocturnal pains in the lower extremities. The immediate response to antisyphilitic treatment confirms the diagnosis. As the left recurrent laryngeal nerve hooks around the arch of the aorta, one interesting possible explanation of the paroxysm is that a beginning syphilitic aortitis at this point caused an irritation to that nerve.

Evanston Hospital.

A METHOD OF TREATMENT FOR NEUROSYPHILIS *

JOHN A. KOLMER, M.D.

PHILADELPHIA

A criticism of the Swift-Ellis system of intraspinal therapy of neurosyphilis may be made because of the minute amounts of arsphenamin detectable as arsenic, carried over in serum secured by drawing blood one hour after the intravenous injection of arsphenamin. This objection is removed by the technic of Ogilvie, who adds arsphenamin, and by that of Marinesco, who adds neo-arsphenamin, to serum in vitro prior to intraspinal injection; but in both methods the patient may be deprived of the beneficial effects of the intravenous administration of these drugs, which probably constitutes a valuable part of the Swift-Ellis treatment. For more than a year, I have used a plan of combined treatment with mercurials and arsphenamin by which I believe that these objections are corrected. In addition, advantage is taken of the very probable value of spinal drainage treatment advocated by Dercum and Gilpin, which is based on the assumption that the rapid withdrawal of cerebrospinal fluid is followed by an increase in the vascularity of the cord, resulting in improved nutrition and facilitating the possible passage of arsphenamin or mercury in the blood to the tissues of the cord and brain and cerebrospinal fluid. Dercum and Gilpin thoroughly drain the subarachnoid space by spinal puncture immediately after the intravenous injection of arsphenamin or during mercurial treatment, but do not inject anything intraspinally; spinal drainage alone has been reported by them as yielding beneficial results.

PLAN OF TREATMENT

Due care is taken to exclude all cases of probable brain tumor:

1. A "course" of treatment covers four weeks; during this period, twenty-four inunctions of mercury, 360 grains of potassium iodid and four combined intravenous and subdural injections of arsphenamin are given, followed by an intermission. Treatment begins with daily inunctions of mercury for one week and the oral administration of 5 grains of potassium iodid three times a day. At the end of this week the first intravenous and subdural injections of arsphenamin are given, and they are repeated at intervals of a week until four have been administered. Mercurial inunctions and potassium iodid are given throughout, excepting on the days when arsphenamin is administered.

* From the Dermatological Research Laboratories.

2. Weinstein, Joseph: Syphilis of the Larynx, *New York M. J.* 104: 165 (July 22) 1916.

3. Kyle, J. J.: Syphilis of the Larynx, *Am. J. Syphilis* 2: 727 (Oct.) 1918.

The urine is examined at least once a week for evidences of renal irritation. If intolerance to mercury or iodid or both develops, the doses are reduced or the administrations are given every other day.

2. On the day when the intravenous and subdural injections of arsphenamin are given, the patient is put to bed at noon and lunch is omitted; light supper is generally permitted, and additional refreshment is given at 9 p. m. if food is desired. If the patient is constipated, a mild cathartic is given the day before to insure an evacuation of the bowels during the morning hours.

3. Six-tenths gm. of arsphenamin is dissolved in 150 c.c. of sterile physiologic sodium chlorid solution prepared of freshly distilled water¹ and a 15 per cent. solution of sodium hydroxid is added until the solution is just completely cleared, the amount of alkali being measured as drops or one-tenth cubic centimeters; after complete neutralization (clearing), three or four drops more of the alkali are added to the solution. *Sterile saline solution is now added to bring the total volume to exactly 200 c.c.;* each cubic centimeter of the solution contains, therefore, 0.003 gm. of arsphenamin, and 1 c.c. is removed to a sterile test tube to be used about one hour later in dose of 0.1 c.c. (0.0003 gm.) for arsphenamizing the serum in vitro.

4. The solution of arsphenamin is now administered by intravenous injection, the dose being approximately 0.6 gm., well diluted.

5. *Immediately after the intravenous injection, 25 c.c. of blood are removed from a vein of the opposite arm with a sterile record or Luer syringe and expelled into a sterile 50 c.c. centrifuge tube fitting the international centrifuge.* The tube has a narrow neck facilitating the use of a sterile rubber stopper, as shown in the illustration, and carries 4 c.c. of a sterile 10 per cent. solution of sodium citrate in physiologic sodium chlorid solution to prevent coagulation of the blood.

6. The blood is at once gently mixed with the citrate to prevent coagulation, and immediately centrifuged at high speed for at least twenty minutes, 10 or 12 c.c. of the clear plasma being pipetted aseptically to a sterile test tube. Sodium citrate may be omitted and the coagulum of blood gently broken up with a sterile glass rod before centrifuging, but from ten to fifteen minutes are required for coagulation before breaking up the clot, and the resulting serum is usually tinged with hemoglobin; the latter, however, is not harmful.

7. *One-tenth c.c. of the solution of arsphenamin held in readiness is now added to the plasma or serum and thoroughly mixed; the dose is 0.0003 gm. ($\frac{1}{3}$ mg.), which is safe for the first injection. Subsequently the dose may be increased to 0.2 c.c. (0.0006 gm.) and*

occasionally to 0.3 c.c. (0.0009 gm.); I have never given a larger amount.

8. The arsphenamized serum is placed in a water bath at 56 c. (132.8 F.) for thirty minutes.

9. Spinal puncture is now performed in an aseptic manner in the lateral posture with a gage No. 19 Babcock needle; the diameter of this needle is about 1 mm., which insures a slow rather than rapid flow of spinal fluid and consequently a gradual drop in cerebrospinal fluid pressure, and the needle fits the record syringe. Preliminary to puncture in the third or fourth lumbar interspace, the skin and subcutaneous tissues are infiltrated with about 1 c.c. of sterile 1 per cent. procain by means of a No. 26 needle, which renders spinal puncture almost painless. Spinal fluid is allowed to flow until about 30 c.c. are secured; at this time, the flow is usually quite slow, many seconds being required for the formation of a single drop. The warm arsphenamized serum (usually from 10 to 12 c.c.) is now slowly injected by gravity or with a record syringe. As a general rule the *slow* injection of 12 c.c. of serum under these conditions is almost painless. Each specimen of spinal fluid is submitted for total cell count (fresh fluid being used), protein determinations, and Wassermann and colloidal gold tests.

10. The foot of the bed is elevated and the patient requested to lie on his back for several hours and to stay in bed until the following day. In every instance but one the patient has been able to leave the hospital the following morning, feeling no ill effects, except the soreness resulting from the needle punctures.

The time required for the operative procedures is about two hours, thus distributed:

(a) About thirty minutes for the intravenous injection of arsphenamin and the withdrawal of blood.

(b) About one hour to secure and arsphenamize the serum.

(c) About one-half hour to conduct spinal puncture, drain the canal, and inject the arsphenamized serum.

The 1 c.c. of solution of arsphenamin carried over in a sterile test tube for arsphenamizing the serum may be used

for this purpose with safety any time within three hours of its preparation.

ADVANTAGES

The advantages of this method may be thus summarized:

1. The patient receives arsphenamin both intravenously and intraspinally.

2. Blood is removed at once, insuring in the serum a larger amount of arsphenamin than is secured after an interval of an hour, as in the Swift-Ellis method.

3. Plasma or serum is secured at once, rendering the complete treatment possible within two or three hours instead of an interval of over night between the intravenous and intraspinal treatments.

4. The removal of from 20 to 30 c.c. of cerebrospinal fluid, followed by the injection of but 10 to 12 c.c. of arsphenamized serum, very probably leaves cerebro-

Centrifuge tube for the aseptic collection of plasma and serum.

1. Kolmer, J. A., and Yagle, E. M.: Hemolytic Activity of Solutions of Arsphenamin and Neo-Arsphenamin (J. A. M. A. 74: 643 [March 6] 1920). The use of sterile physiologic sodium chlorid solution instead of water, and the addition of only a slight excess of alkali over that required for complete clearing of the solution instead of one third excess, reduce the hemolytic activity of the solution, which is probably a factor of importance in the intravenous injection of 200 c.c.

spinal fluid pressure reduced for some time, producing increased vascularity of the cord and probably also of the brain, with the beneficial effects ascribed alone to spinal drainage. Indeed, injection of arsphenaminized serum within an hour of the intravenous injection may increase extravasation from the meningeal vessels by reason of irritation produced by the serum and arsphenamin in the subarachnoid space, in addition to the increased vascularity and transudation ascribed to reduction alone of cerebrospinal fluid pressure.

5. The patient receives the benefit of treatment with mercury and iodids and of spinal drainage conducted while under the influence of these antisyphilitic medicinals.

CONTRAINDICATION TO THE METHOD

The disadvantage of the method (encountered once in my experience) is the inadvisability of giving the intraspinal treatment in the presence of a reaction following the intravenous injection of arsphenamin. The administration of arsphenamin as described has been only exceptionally followed by a reaction of flushing and chills, and with one exception the patients have expressed a desire for the intraspinal treatment and have enjoyed a good sleep and rest, toward which a psychic element due to the realization that the ordeals were over has contributed in no slight degree.

In the one case in which a reaction following the intravenous injection of arsphenamin prevented the intraspinal treatment, a second specimen of blood was drawn later in the afternoon after the subsidence of the reaction and placed in a refrigerator over night, followed by separation of the serum next day and arsphenaminizing by the addition of 0.1 c.c. of a solution of arsphenamin prepared by dissolving 0.1 gm. in 30 c.c. of 0.8 per cent. salt solution, neutralizing with a normal solution of sodium hydroxid (about 4 per cent.)² adding two or three drops more of alkali, and then salt solution to bring the total volume to exactly 33 c.c.; 0.1 c.c. of this solution added to the serum represents 0.0003 gm. of arsphenamin ($\frac{1}{3}$ mg.). After heating the arsphenaminized serum at 56 C. for thirty minutes, spinal puncture, drainage and intraspinal injection were conducted as described above, and the patient was kept in bed for another twenty-four hours, which I regard as a wise precaution after intraspinal treatment or even simple spinal puncture and the removal alone of 5 c.c. or more of spinal fluid for laboratory examinations.

1720 Lombard Street.

2. A normal solution of sodium hydroxid, or one of approximately 4 per cent. strength, is better than a 15 per cent. solution for the purpose of preparing solutions of small amounts of arsphenamin, as 0.1 gm.

Influenza in Alaska.—The annual report of the governor of Alaska shows that thousands died in an influenza epidemic through want of care. Influenza broke out early in October in practically all the coastal towns following the lines of steamer travel. Travel to the interior was stopped and so it escaped the outbreak. It is estimated that there have been 1,500 deaths, chiefly among the natives, on the Seward Peninsula and vicinity. There were over thirty deaths among the passengers on the last trip of the steamer *Victoria*. At Kodiak and on Cook Inlet the mortality was extremely high. Whole villages of Eskimos lost their entire adult population. Many infants were frozen in their dead mothers' arms. Medical relief was given where possible; destitution was relieved, and the orphan children gathered up and placed in institutions until appropriations should become available for their permanent care. The burial of dead natives alone cost approximately \$20,000.—*U. S. Bull.*, Dec. 15, 1919.

AN ANALYSIS OF FIFTY-SIX CASES OF BREECH PRESENTATION

DESCRIPTION OF A METHOD OF DELIVERY IN WHICH
MANUAL EXTRACTION OF EXTENDED ARMS
IS RARELY NECESSARY

HARBECK HALSTED, M.D.

NEW YORK

These cases of breech delivery occurred at the Manhattan Maternity and Dispensary on the services of Drs. J. Clifton Edgar, Austin Flint and R. E. Brown, during my time as resident surgeon (June 3, 1915, to July 1, 1916).¹ In cases of fetal death, the necropsies were performed by Dr. L'Esperance of Cornell University.

A large number of the deliveries of the Manhattan Maternity and Dispensary are performed on the outdoor service, by interns whose service is only three months. Therefore an effort was made to find or devise a standard method of breech delivery that was as near "fool proof" as possible.

As a large part of the delay in breech delivery is due to the more or less common practice of manually going up past the head through the pelvic inlet to deliver extended arms, an attempt was made to find a method whereby this was seldom, if ever, called for. The use of the delivery described herewith has practically eliminated this necessity, except when there is a nuchal hitch.

METHOD OF DELIVERY

Until the breech delivers from the vulva, the procedure is the same as with any other breech delivery. As soon as the breech delivers, the child is covered with a warm, wet towel, and gentle traction is made downward and backward, assisted by pressure from above, until the umbilicus is delivered; then a loop of the cord is pulled down, the child is grasped about the pelvic girdle, and strong traction is made downward and backward. The bisacromial diameter of the body is kept in the anteroposterior diameter of the maternal pelvis until the anterior scapula is seen to slip under the symphysis; at this point it is very easy to deliver the anterior arm from the vagina. Now the child's body is lifted over the mother's abdomen, whereupon the posterior arm will slip out. The occiput is allowed to rotate under the symphysis, and the body to go with it. The child is placed along the right forearm, the index finger is put in the child's mouth, with the fingers of the left hand over the child's shoulders, care being taken not to fracture the clavicles, and moderate traction is made downward and backward until the mouth can be delivered by flexion upward. After the mouth is delivered, one should go slow unless there is some indication for speed.

Before the delivery is begun, the position of the child should be accurately made out so that there will be no danger of allowing the occiput to rotate posteriorly. This can be prevented by always delivering the anterior hip first and assisting the rotation of the occiput forward by rotating the body in the proper direction. In left sacral positions, the child's body should be rotated to the right and anteriorly. In right sacral positions, to the left and anteriorly.

Before any traction is made from below, an assistant makes firm pressure on the child from above; this pressure is continued until the child's mouth is delivered. It is made in such a manner that the head will remain flexed on the chest and the arms will not extend. This pressure is a very important part of the delivery.

The main points to remember are:

1. As soon as any traction is made, it should be made downward and as far backward as possible. To do this it is

1. The reason I did not complete this paper earlier is that I have been on active duty in the United States Naval Reserve Forces for two years.

always necessary to have the woman's hips on or just over the edge of the operating table, or, if done in a home, over the edge of a kitchen table. The delivery will be facilitated, especially the traction backward, if the legs of the woman are held by two assistants so that the thighs are slightly flexed on the abdomen and the legs on the thighs with the feet on a level with the buttocks, and not in the ordinary lithotomy position with the legs in stirrups. A breech delivery should never be performed in bed.

2. One should not go up after the extended arms, unless certain that there is a nuchal hitch, that is, an arm caught back of the occiput; for in all other positions the arms will squeeze through the pelvic inlet with sufficient traction from below.

3. Firm pressure should be maintained from above, applied in such a way as to keep the head flexed.

No originality is claimed for this method, but if it is used conscientiously, breech delivery will lose a great many of its terrors, and the fetal mortality will be decreased.

The method was used in nearly all of the cases here reported. Versions and multiple births are not included in this series.

The position was left sacro-anterior in thirty cases; left sacroposterior in one; right sacro-anterior in twenty-one, and right sacroposterior in four. As the majority of these patients lived in tenements, and so were not often seen early in labor, the number of sacroposterior positions reported is probably much too small.

REPORT OF STILLBIRTHS

In this series there were nine stillbirths.

CASE 1 (Breech L. S. A. 198). The fetus, born at the seventh month, was macerated and weighed 3 pounds.

Necropsy: The fetus was too decomposed for microscopic section.

CASE 2 (Breech L. S. A. 204). The mother, a quintipara, lived in a tenement house. When the intern arrived at the bedside, all the baby had been born but the head, and although this was very easily delivered it was too late, and the baby was dead.

Necropsy: The child was a large, normally developed boy. There were punctate hemorrhages in the thymus, lungs, liver and suprarenals, and fluid blood. The thymus was very large, almost double normal size. This may have been a predisposing factor in the cause of death.

Anatomic Diagnosis: Asphyxia in new-born; fluidity of blood; enlarged thymus.

CASE 3 (Breech R. S. A. 115). The fetus was a marked specimen of an encephalic monster that never breathed. The labor was very easy, lasting only one hour and fifty-five minutes.

CASE 4 (Breech L. S. A. 206). The mother was a primigravida. The membranes ruptured during the first stage. Labor lasted thirteen hours and forty minutes. The head stuck at the pelvic inlet for a full ten minutes. The heart was beating at birth, but the baby could not be resuscitated. The arms were flexed on the chest.

CASE 5 (Breech L. S. A. 209). The mother, aged 19, was a secundigravida. The membranes ruptured at the second stage of labor. The delivery was spontaneous after a labor lasting eight hours and forty-five minutes. The cord was around the baby's neck. The baby weighed 7 pounds and 8 ounces.

CASE 6 (Breech L. S. A. 211). The mother was a tertigravida. The two previous deliveries were instrumental. The baby weighed 11 pounds and 11 ounces. The patient was ten days overdue. The membranes ruptured two days before the onset of labor. Labor lasted seventeen hours and eighteen minutes. Delivery was very difficult. The arms were extended, gone up after, and manually extracted. The head was extracted with difficulty. This stillbirth was due to the excessive size of the child.

Necropsy: The baby was a very large boy with excessive development of fat and purplish discoloration of the entire skin. The liver was large and showed multiple hemorrhages. The spleen was large and congested. The suprarenals were entirely destroyed by hemorrhage, forming almost a hemorrhagic sac. The kidneys were deeply congested. The bases of both lungs showed hemorrhages. The remaining portions of the lungs showed some areas of emphysema, as if a pulmotor had been used. The thymus was large. The brain showed diffuse hemorrhage over its entire surface.

Anatomic Diagnosis: Asphyxia; overdevelopment.

CASE 7 (Breech L. S. A. 212). The mother was a quadrigravida with a generally contracted pelvis. The baby weighed 9 pounds and 11 ounces. The membranes ruptured early in the first stage. The arms were extended, gone up after, and manually extracted with great difficulty. Then the head stuck at the pelvic inlet for some time. In this case we had a large child and a small pelvis.

Necropsy: The body was that of a full term, well developed girl. The organs, especially the kidneys and the suprarenals, showed congestion. There were punctate hemorrhages in the lungs and the thymus. The heart was normal. The brain showed diffuse meningeal hemorrhages.

Anatomic Diagnosis: Cerebral hemorrhage; asphyxia.

CASE 8 (Breech L. S. A. 222). The mother had had ten previous labors. The delivery seemed very easy, but the baby could not be resuscitated. The membranes ruptured in the first stage. The labor lasted nine hours and forty minutes. The arms were extended, but caused no delay.

Necropsy: The child was a well developed girl. There were no skin lesions. The area of aeration in the lungs was small; the remaining portion was atelectatic. The bronchi were filled with thick, greenish, tenacious mucus. There were small punctate hemorrhages in the thymus. The other organs were apparently normal.

Anatomic Diagnosis: Asphyxia; mucous plugs in the bronchi.

CASE 9 (Breech L. S. A. 227). The labor occurred four weeks prematurely in a quintipara. The labor lasted four hours and fifteen minutes, and terminated spontaneously. The baby was born dead. It weighed 6 pounds and 12 ounces.

OTHER DATA

No babies that were born alive died while still under our care. There were fourteen primiparas and forty-two multiparas, the latter being thus divided: secundiparas, 9; tertiparas, 9; quadriparas, 6; quintiparas, 9; sextiparas, 2; septiparas, 2; octiparas, 2, and 1 nonipara, 1 decipara and 1 undecipara.

The ages of the mothers ranged from 18 to 44 years. The age did not seem to have any influence either on the frequency or on the ease of delivery.

The fetal heart sounds were mentioned as being heard fourteen times above the level of the umbilicus; at the level of the umbilicus, six times, and below the level of the umbilicus, twenty times. It was not heard seven times, and not mentioned nine times.

The living babies varied from 3 pounds and 8 ounces to 10 pounds. The stillborn babies' weights ranged from 3 pounds (a macerated premature baby) to 11 pounds and 11 ounces. The average weight for all cases was 7 pounds and 2 ounces; for the stillborn babies, 7 pounds and 12 ounces, and for babies born alive, 7 pounds.

No note was made of whether or not the arms were extended unless they gave trouble. They were manually extracted in two cases. (These were both described under stillbirths, Cases 6 and 7.) There is one case described in which there seems to have been a nuchal hitch:

The breech was born as usual up to the shoulders, the scapula appearing from under the symphysis before reaching for the anterior arm. This, the anterior (left), was extended

and lay behind the occiput. The posterior arm was delivered first in the usual manner, then the anterior flexed and pulled down.

The term "usual manner" means the delivery described above.

The after-coming head was mentioned as being delivered by the Smellie-Veit method in twenty-four cases. The delivery was recorded as spontaneous in twelve cases. No mention was made of the delivery of the head in twenty cases. No craniotomy was done on an after-coming head.

The forceps were never applied to either the head or the breech, although they were frequently held in readiness when we expected trouble. The only three cases in which the head stuck and forceps might have been of help occurred in tenements when forceps were not at hand. It might be a good rule always to have forceps ready before starting a breech delivery.

Chloroform was used in twenty-six cases, ether in one case. There was no anesthesia in nineteen cases. No mention was made as to any anesthesia being used in the remaining eleven cases. I myself prefer the patient well anesthetized for the actual delivery.

The longest labor in the series lasted thirty-three hours and fifteen minutes. This was in the case of a primipara, aged 23. The membranes ruptured one day before she went into labor. Finally, a breech extraction was done and she was torn through the sphincter ani. The shortest labor was two hours and fifteen minutes. This occurred in a tertipara. The baby weighed 5 pounds and 9 ounces. The average length of labor in the primigravidae was seventeen hours and four minutes. The average length of labor in the multigravidae was nine hours and eight minutes. From these figures it would seem that the length of labor was not much influenced by the presentation.

The time of rupture of membranes was: in the second stage of labor, seventeen cases; in the late first, ten cases; during the first stage, ten cases; at the onset of labor, one case, and before labor began, three cases, in one of these two days and in another one day, before labor began. The time of rupture was not mentioned in fifteen cases.

There were only two cases of definite prematurity. In both, the baby was born dead; one was macerated. One case was ten days past term. This baby was also born dead after a difficult labor.

Of lacerations of the perineum, in the primigravidae there were six first degree; two second degree, and one third degree; in the multigravidae, four first degree and one second degree. It seems to me that there were as few lacerations in this series as there would have been in a similar number of vertex deliveries, with the exception of the third degree laceration.

In these cases, deformity of the pelvis seemed to play little part, as only one woman is recorded as having any deformity, and she only a moderately generally contracted pelvis.

One baby was a monster; two had club feet; and one of these also had spina bifida. Aside from these, there were no marked abnormalities.

CONCLUSIONS

1. The most dangerous condition in breech delivery seems to be disproportion between the size of the child and the pelvis.

2. Deformities of the pelvis and child did not seem to play much part in determining the breech presentation.

3. Early rupture of the membranes is a serious happening.

4. Manual extraction of extended arms is seldom indicated. Manual extraction of the arms was used twice in this series, and in both cases the child was stillborn.

221 West Fifty-Seventh Street.

DIGESTIBILITY OF STEAM-COOKED SOY BEANS AND PEANUTS*

ARTHUR D. HOLMES, M.D.

Specialist in Charge of Digestion Experiments, Office of Home Economics

WOODSTOWN, N. J.

The unusual demand for foods, coupled with the high price of labor and fertilizer, makes it necessary that each acre of land devoted to food crops produce the maximum amount. From an agricultural standpoint the legumes are considered a profitable crop, since they enrich the soil with nitrogen while producing valuable food for man and beast. The legumes in general have long been important sources of food, and on account of their high protein content are sometimes referred to as the "poor man's beefsteak"; but two valuable kinds, soy beans and peanuts, have been relatively little used in this country in the human dietary.

Studies of the food value of soy beans and peanuts have supplied considerable data relative to their dietary importance. A comparison¹ of the composition of legumes in general with the composition of soy beans and peanuts shows that the latter are much richer in protein and fat, the expensive constituents of the diet, and accordingly from this standpoint are very valuable. For dietary purposes, however, the nature as well as the quantity of protein is of importance, since incomplete proteins cannot serve over long periods of time as the sole source of tissue-forming material.

Studies of the amino-acids from legume proteins made by Osborne and co-workers² and by Johns and Jones³ have shown that those from the proteins of soy beans and peanuts are in kind and proportion such as are believed to be essential to normal development. Such was not the case with the other legume proteins studied.

This belief is confirmed by biologic studies. McCollum, Simmonds, and Pitz,⁴ in discussing the effects of feeding laboratory animals on a diet rich in navy beans, say: "We feel safe in saying that this legume should under no circumstances form a principal part of any relatively monotonous diet." McCollum and Simmonds⁵ conclude that "the protein mixture from maize 80 and navy beans 20 per cent. has just about one-half the biological value for growth that the total protein mixture in milk possesses." Daniels and Nichols⁶

find that "the protein of the soy bean appears to be quite as valuable as the casein of milk." Osborne and Mendel,⁷ in discussing the use of soy beans as food, state that "the proteins of the soy bean, unlike those of the other leguminous seeds thus far investigated, are adequate for promoting normal growth." Referring to reproduction of laboratory animals restricted to soy beans as a source of protein, these investigators⁸ say: "On diets containing either the soy-bean meal or the commercial soy-bean meal, together with fats and 'protein-free milk' or our 'artificial' salt mixture, several broods of vigorous young have been produced, and these young have grown normally on diets the same as those on which their parents were raised. This is a further demonstration of the nutritive efficiency of this legume, in striking contrast with the adverse results obtained with kidney beans and garden peas." Daniels and Loughlin,⁹ in discussing feeding experiments with peanuts, report: "Good growth was secured also with a ration supplying 15 per cent. protein from the peanut meal. The proteins of peanuts are comparable to those of the soy bean, since it has been shown that both legumes supply the essential amino-acids in sufficient amounts for normal growth and reproduction."

Owing to the convincing results of a large number of carefully controlled metabolism studies with laboratory animals, students of nutrition are agreed that in order to maintain the well-being of the body through the processes of growth, maintenance and reproduction it is necessary that the diet supply in addition to an adequate amount of protein, fat, carbohydrate, and mineral matter, three as yet unidentified food accessories, which have been designated fat-soluble A, water-soluble B, and water-soluble C. In a number of the studies referred to already and in reports of others,¹⁰ the value of legumes as sources of these accessories or vitamins is reported. Fat-soluble A is nearly, if not entirely, lacking in all legumes thus far reported on with the single exception of the soy bean. Water-soluble B is found in satisfactory amounts in all thus far investigated. Water-soluble C appears to be lacking in the dried seeds of all the legumes studied, but to be abundant during the sprouting state. Whenever present, it appears to lose its dietary efficiency when cooked at a temperature and under pressures such as were used in the experiments described in the present paper.

Studies of the digestibility of legume proteins have been made by Rubner,¹¹ Malfatti,¹² Prausnitz,¹³ Snyder,¹⁴ Richter,¹⁵ Woods and Mansfield,¹⁶ and Wait,¹⁷ and the general conclusion to be drawn from the experimental data obtained by these investigators is that while the legume proteins are fairly well utilized

by the human body, comparing favorably in this respect with the cereal proteins, they are not so completely utilized as the animal proteins supplied by meats, eggs and milk. Few studies have been made of the digestibility of proteins present in soy beans and peanuts. Oshima¹⁸ reports three experiments in which the average digestibility of the total protein of a diet of tofu (soy-bean curd) and rice, of which 83 per cent. was soy-bean protein, was 95 per cent. Mendel and Fine¹⁹ found the digestibility of soy-bean protein to be 85.3 per cent., as compared with 77.9 per cent. for that of the navy bean. Lyman and Bowers²⁰ have also studied the digestibility of soy-bean meal and report two digestion experiments with bread made with soy-bean meal in which the digestibility of the protein averaged 91.1 per cent. No data were found in the literature consulted regarding the digestibility of peanut protein.

During the period of unprecedented demand for foods occasioned by the recent war, it appeared to me that soy-bean and peanut press cakes could well be utilized for food purposes, especially the cakes that resulted from "cold pressing" sound soy beans and peanuts. Accordingly, experiments were conducted in the Office of Home Economics Laboratory of the Department of Agriculture to determine the digestibility of the proteins supplied by these legumes when the press-cake flours were blended with wheat flours and served in the form of an unleavened bread. Seven experiments with soy-bean flour and eleven with peanut flour showed the proteins to be 85.3 per cent. and 85.8 per cent. digested, respectively.²¹ In view of the high digestibility of soy beans and peanuts and the possibility of using these legumes as vegetables served in the same manner as navy beans and garden peas, additional tests seemed desirable, and the experiments here discussed were conducted to determine the digestibility of soy beans and peanuts when cooked under conditions approximating those employed in the preparation of commercial canned beans.

GENERAL PROCEDURE

For these experiments whole mammoth yellow soy beans grown at the government field station at Arlington, Va., were obtained from the Bureau of Plant Industry, and raw shelled peanuts were bought from a local dealer. The soy-bean and peanut experiments were carried on separately, but the general procedure was the same. The peanuts were skinned and divided into half kernels, and both beans and peanuts were thoroughly washed and placed with sufficient salt and water in a pressure cooker under 15 pounds pressure for two hours, at which time they were thoroughly cooked.

The diet, so chosen that the accessory foods should supply a limited amount of protein and at the same time be typical of a simple mixed diet, consisted of soy beans or peanuts, bread, butter, sugar, oranges, and tea or coffee. Tea and coffee were taken hot; the rest of the diet was eaten cold. The experimental periods were of three days' duration. The six subjects were men from 19 to 41 years old who had acquired considerable experience in this type of work. They were informed that a large consumption of soy beans or

peanuts was desired and that they could follow individual inclination in regard to the remainder of the diet.

A record of the weight of food consumed and the weight and chemical analysis of feces resulting from the experimental diet supplied data for calculating the coefficients of digestibility of the ration as a whole. The digestibility of the protein supplied by the soy beans or the peanuts was estimated by making correction for the undigested protein remaining from the accessory foods according to a method fully outlined in previous papers.²² It was assumed that the proteins of bread,²³ butter,²⁴ and oranges²⁵ were 88, 97 and 85 per cent., digested, respectively.

STEAM-COOKED SOY BEANS

The six digestion experiments that were conducted with soy beans were divided into two series of three tests each. The first series commenced on January 29 and the second on April 9. Uniform experimental conditions were maintained in both series, the soy beans were all from the same lot, and none of the subjects assisted in more than one experiment. The cooked beans were soft and tender, but in many the thin skin remained unbroken.

The results of these experiments are summarized in Table 1.

TABLE 1.—DIGESTION EXPERIMENTS WITH SOY BEANS
(STEAMED) IN A SIMPLE MIXED DIET

Experiment Number	Subject	Digestibility of Entire Ration			Estimated Digestibility of Soy-Bean Protein Alone, per Cent.
		Protein, per Cent.	Fat, per Cent.	Carbo- hydrate, per Cent.	
769	P. K.	78.8	88.0	97.0	74.8
772	J. C. M.	79.5	90.3	95.9	76.0
773	W. O'C.	84.5	88.8	97.9	82.7
835	J. F. C.	85.2	88.6	98.3	82.9
837	T. G. H.	80.1	84.5	96.5	80.0
838	F. A. K.	85.7	90.0	98.1	83.1
Average.....		82.3	88.4	97.3	79.9

The ration as a whole supplied 103 gm. of protein, 114 gm. of fat, 415 gm. of carbohydrate, and 3,100 calories of energy for each man daily. Its digestibility was found to be 82.3 per cent. for protein, 88.4 per cent. for fat, 97.3 per cent. for carbohydrate, and 79.9 per cent. for soy-bean protein, a value somewhat lower than the 85.3 per cent. previously reported²⁶ for protein of soy-bean flour. One subject ate an average of 478 gm. of soy beans daily for three successive days and experienced no physiologic disturbance.

STEAM-COOKED PEANUTS

Six digestion experiments were conducted with peanuts cooked as already described. The peanuts prepared in this manner were rather mealy, very palatable, and apparently thoroughly cooked; but while they still retained their original form (half kernels), the interior cellular structure was obviously somewhat altered, for the peanut kernels could be reduced to a pasty mass by very slight pressure. A summary of the results of the experiments with peanuts is given in Table 2.

Considering the diet as a whole, the subjects ingested 92 gm. of protein, 162 gm. of fat, 354 gm. of carbohydrate and 3,240 calories of energy daily; the digesti-

bility was found to be: protein, 90.7 per cent.; fat, 83 per cent.; carbohydrate, 99.0 per cent. One subject consumed an average of 457 gm. of peanuts on each of three successive days without noting any physiologic disturbance. Contrary to expectations, the digestibility of the protein of steam-cooked peanuts, 92.8 per cent., was much higher than 85.8 per cent., that previously reported²⁷ for the digestibility of the protein of peanut

TABLE 2.—DIGESTION EXPERIMENTS WITH PEANUTS
(STEAMED) IN A SIMPLE MIXED DIET

Experiment Number	Subject	Digestibility of Entire Ration			Estimated Digestibility of Peanut Protein Alone, per Cent.
		Protein, per Cent.	Fat, per Cent.	Carbo- hydrate, per Cent.	
854	J. F. C.	90.8	80.2	99.2	92.7
856	J. J. D.	90.0	81.1	99.2	94.0

flour. No data are available for ascertaining whether the peanut flour if steam-cooked would have been equally well assimilated. These results show that steam-cooked peanuts, which furnish relatively large amounts of essential amino-acids, are of unusual value for human food.

COMPARISON OF THE DIGESTIBILITY OF SOY BEANS AND PEANUTS WHEN STEAM-COOKED AND WHEN GROUND INTO FLOUR

The results of the study of the digestibility of steam-cooked soy beans and peanuts and flours prepared from soy-bean and peanut press cakes are summarized in Table 3.

The digestibility of the protein supplied by steam-cooked soy beans is apparently less than that of the protein of soy-bean flour, owing, perhaps, to the fact that the thin unbroken skin that surrounds the cooked soy bean is impervious to the action of the digestive juices. It also may be due to difference in cooking.

The digestibility of the protein supplied by steam-cooked peanuts was found to be higher than that of

the protein of peanut flour; but since no data are available regarding steam-cooked peanut flour, it is impossible to judge whether the particular cooking process is responsible for the higher digestibility of the steam-cooked peanuts.

CONCLUSIONS

While the carbohydrate content of the diet was well utilized in each series of experiments, it was found

22. Bull. 470, U. S. Dept. Agr., 1916, p. 7. Bull. 525, 1917, p. 4. Bull. 717, 1918, p. 15.

23. An average of forty-five unreported experiments with white flour.

24. Bull. 310, U. S. Dept. Agr., 1915, p. 21.

25. Connecticut Storrs Sta. Report, 1899, p. 104.

26. Bull. 717, U. S. Dept. Agr., 1918, p. 18.

27. Bull. 717, U. S. Dept. Agr., 1918, p. 24.

that the carbohydrate of the entire diet of which steam-cooked peanuts formed a part was especially well utilized, 99 per cent. being digested.

The fact that large quantities of soy beans and peanuts were consumed daily for three successive days, without causing any physiologic disturbances, indicates that these foods cooked for two hours by steam at 15 pounds pressure are well tolerated by the human body.

The results of this investigation, considered in connection with the previously reported data regarding the nutritive and biologic values of these two legumes, gives evidence to justify the belief that soy beans and peanuts are especially valuable for human food, as compared with other legumes that have been studied with the same thoroughness.

Clinical Notes, Suggestions, and New Instruments

COMPLETE CLOSURE OF THE URINARY BLADDER AFTER COAGULATION OF TUMORS

GUSTAV KOLISCHER, M.D., AND J. S. EISENSTADT, M.D., CHICAGO
Attending Urologist and Associate Urologist, Respectively,
Michael Reese Hospital

It has always been a cause of regret to genito-urinary surgeons that in most operations on the bladder it is impossible to deliver a finished product on account of the necessary or supposedly necessary tubal drainage of this viscus. This was one of the more important reasons for their taking up so enthusiastically the cystoscopic endovesical methods in the treatment of bladder tumors. Endovesical treatment today includes fulguration, galvanocauterization and diathermy.

There are cases, however, in which fulguration is not advisable on account of the character of the growth, or in which even the repeated application of the galvanocautery or the diatherm through the operative cystoscope is not successful, or cases in which, on account of the location or the extent of the tumor, an endovesical intervention *a priori* could not be expected to be sufficient.

The superiority of destruction by heat of vesical tumors over the excision with the knife is becoming more and more appreciated by urologists. The problem forced itself on our surgical judgment as to how to combine the advantages of this procedure with the elimination of the disagreeable features of the postoperative vesical drainage. In this endeavor we were guided by experiences in developing a method of complete closure of the bladder which quite constantly ensures primary union, even in the presence of vesical infection.

The essential features of this method are mattress sutures of the bladder wall with inversion of the mucosa edges, which union is reenforced by whipping over a simple continuous suture, and thorough subfascial drainage accomplished by placing a narrow rubber tube under the fascia of the recti and parallel to the incision. The ends of this tube are brought out at each end of the skin wound. The bladder is opened by suprapubic cystotomy in the usual manner. The seat of the tumor is freely exposed by retractors made of fiber or hard rubber, and the coagulation is thoroughly accomplished by the galvanocautery or by diathermy. The bladder and abdominal wall are then closed completely, except for the subfascial drainage.

The patient, after operation, urinates spontaneously or is catheterized at regular intervals. A permanent catheter is not used because of the danger of urethritis, vesical irritation and ascending infection. If cystitis occasioning marked or moderate symptoms is present, 20 per cent. argyrol solution is instilled into the bladder twice a day. The subfascial drainage tube is removed after twenty-four hours. The bladder incision and abdominal wound are usually entirely healed in seven or eight days. The condition and appearance of the former site of the tumor depends on the type of the destruc-

tive agent used. An eschar produced by the galvanocautery is exfoliated in from five to eight days, while that produced by the diatherm sloughs in from ten to sixteen days.

If malignancy is suspected or proved, radium or mesothorium is inserted into the bladder cavity by means of a urethral carrier.

It seems that the advantages of this procedure over the routine method of vesical drainage are obvious. Whether this technic is applicable to extensive carcinomas involving the base of the bladder remains to be proved by further experience.

A SUBSTITUTE FOR OPEN OPERATION IN SOME IRREDUCIBLE FRACTURES

J. STANLEY WELCH, M.D., LINCOLN, NEB.

Pursuant to the surgical principle of accomplishing most in the least radical manner, we have resorted to a simple method of reduction in several cases of fracture in which open operation seemed obligatory.

The mechanism of the reduction is a lever in the form of a small, strong, steel probe acting between the displaced fragment ends and retained in situ by the plaster cast. It is resorted to under surgically aseptic conditions with anesthesia, while being observed under the fluoroscopic screen. The instrument is introduced through the iodized skin on the side of the extremity most remote from large vessels. Its end is guided by watching in both axes under the fluoroscopic screen. It is carefully placed between the fragments in such a manner as best to pry them back into apposition. Then when they are reduced, the instrument may be withdrawn; or, in the event of a recurrence of displacement, it is surrounded with a small sterile dressing and the plaster splint is immediately applied. When this is firmly set, the protruding part of the instrument is cut off with a hack saw. No infection should occur, and in from seven to ten days we remove the probe with a pair of pliers without a change of the cast unless otherwise desired. No death of bone should occur in this time with the degree of pressure here necessary.

It is an occasional experience to find, in a fracture of both bones of the forearm or leg, an irreducible condition of one or both bones. It is a frequent experience to find that, once reduced, they do not so remain. We believe this simple method will satisfactorily retain many such fractures and prevent a much more radical operation or a more cumbersome dressing in extension.

PATHOLOGIC LYING IN A CRIMINAL*

A PSYCHOPATHIC PERSONALITY

N. S. YAWGER, M.D., PHILADELPHIA

Consulting Neurologist, Pennsylvania Eastern State Penitentiary

The case here reported shows emphatically the character deviation of a pronounced and persistent fabrication, abnormal in type; this is a degenerate condition and almost invariably accompanies other forms of degeneracy, as shall be illustrated in our subject, who was likewise guilty of the most hideous crimes.

It was Delbrück¹ who definitely isolated this form of falsification, and for it he coined the term "pseudologia phantastica," a name that has since been adopted by many German writers; others have styled the disorder "mythomania."

Kraepelin² under the caption of "pathologic liars and swindlers" says: "Here we have in general to deal not only with a hyperexcitability of the imagination and defective faithfulness of the memory, but also with a certain unsteadiness in the sphere of the emotions and of the will."

Swindling has not entered into the activities of our criminal, but this may have been due to lack of opportunity—he has long been a convict.

* Read before the Philadelphia Neurological Society, Jan. 23, 1920.

1. Delbrück, A.: Die pathologische Lüge und die psychisch abnormalen Schwindler, Stuttgart, 1891: p. 131.

2. Kraepelin, Emil: Psychiatrie, Leipzig, Johann Barth 2: 831, 1904.

There is a poverty in English literature on the subject, but in this country Healy³ has contributed a monograph; his studies have for the most part been juvenile cases, and he frequently found accusation accompanying this type of prevarication. In our individual, who is an adult, accusation is a rather pronounced feature.

Ely⁴ reports the case of a young woman referred by the juvenile court who it was said had always been feeble-minded. She ran away from home early in life and was grossly immoral. One of her stories was to the effect that when about 16 years old she became pregnant with an illegitimate child; her confinement was recounted most vividly, together with her subsequent love for the child. There was no physical evidence that she had ever been pregnant, and it was regarded as one of her many inventions.

The life history of our criminal reveals an astonishing amount of character deviation. In addition to the abnormal fabrication, there were two attempts at homicide, one successful; three attempts at suicide; probably rape, and possibly simulation of insanity. Since real names are inadvisable, those given are fictitious.

Francis, the prisoner, is 42 years of age and was born in Lithuania. He said his mother's husband was a builder of church organs whose work kept him much from home, and, during one of these absences, she became pregnant with this son; but this statement, which blackens his mother's character and stamps him with illegitimacy, is not above question.

After passing through the Russian gymnasium he began work as a telegraph operator, but his restless nature tired and he entered a military academy; on leaving there, he enlisted in the Russian guard, and it was during this service that he became infatuated with a Lithuanian girl called Marie, which was the determining cause of his blighted career, since it led to her death and his life imprisonment.

A difference in religion had led the father of this girl to forbid Francis' attention to her. However, absenting himself from the army without leave, he called at her home, but the father ordered him away. In a frenzied moment he pulled an ornamental hatchet from the wall and hit Marie in the head; she was not badly injured and recovered. He then cut his own throat, and after being taken to the hospital made a determined effort to tear open the wound. When sufficiently improved, he was tried for attempt to kill, attempt to commit suicide, and for desertion from the army. He was sentenced to imprisonment. With the birth of the czar's son and the granting of amnesty, Francis was placed on parole. In an effort to escape him, Marie came to America; but he violated his parole and followed. Arriving in Philadelphia in March, 1907, he located her. Marie, after considerable persuasion, was induced to come to his room, where, as she subsequently charged, he ravished her. He countered with the charge of theft—that she had stolen his pocketbook. This he told me was a lie and that he had invented the story for revenge. From his knowledge of sexual matters, Francis also challenged her virginity. He was arrested and placed in Moyamensing prison. Subsequently, the affair was quashed by his agreeing never again to attempt to see her. On release, he failed in his promise and endeavored to get her consent to matrimony; she positively refused whereupon, he became desperate and determined to kill her. The act was consummated in April, 1907. Marie was shot four times, and he then shot himself. Both were taken to the Pennsylvania Hospital. Marie died on the way. He lay unconscious for four days, and when sufficiently recovered, was again placed in Moyamensing.

The complicated mental picture then presented led to one of the most remarkable medicolegal cases of our courts. The prisoner has told me that he was not insane at the time but had been advised to "play crazy," and that he acted the part. The verdict was "guilty of murder in the first degree but now a lunatic." He was ordered to Norristown State Hospital and detained for one year, after which, he was returned to Moyamensing.

Technical difficulties then led to his appearance before different courts, until finally a jury rendered a verdict of first degree murder. The case was appealed, but the decision was sustained. Five different times the day for execution was set. Finally, on request, a member of the state committee of lunacy reviewed his mental history, examined him, and reported to the governor. After careful consideration, this able report recommended the extension of clemency, with the result that the death sentence was commuted to life imprisonment, and he was ordered to the Eastern State Penitentiary.

Now as to his fabrications: All who come in contact with Francis aver that he is a stupendous liar; but his most astonishing invention was while in Moyamensing. It related to another atrocious murder in which the prisoner said he was implicated, and which he attempted to tell a priest; the latter refused to confess him until the authorities had been apprised of his crime. This he acceded to by describing the murder of a man named Galwitz by another named Zellner. The prisoner stated he had witnessed this murder and stood by while a 5-foot grave was dug and the body placed therein. The cause of this crime was jealousy; both men had been intimate with the girl Marie, and this led one to kill the other. A detective was detailed to investigate the case, and the spot was located; but the presence of water rendered it a physical impossibility to dig a grave there. The whole matter proved to be a fabrication, and the case was dropped in the belief that the prisoner was simply "exercising his imagination." The man still recalls the circumstance and regards it a good joke.

Physical examination discloses no positive anatomic stigmas. In fact, judging from nature's evidence, the prisoner measures up well. In appearance he is tall, erect and finely proportioned; his head is well shaped and his countenance is rather inviting; he is polite, quick-witted, of the utmost assurance, an incessant talker, and with a great deal of general but superficial knowledge which he uses with considerable linguistic ability. In his personal habits he is clean, industrious and methodical, attributes which are noticeably rare with the criminal class.

The only neurologic finding is a slight motor paralysis caused by severance of the temporal branch of the temporo-facial division of the right facial nerve which resulted from his attempt at suicide in 1907. A roentgenogram reveals the presence of a foreign body in the left temporal region of the brain, probably inoffensive, despite the prisoner's statement that he cannot lie on his left side; cell-mates have told me that he lies equally well on either side; or, as an Irish prisoner expressed it, "the man lied on all sides."

Francis is suspicious, and is constantly making accusations against overseers and cell-mates; this has led to his being tried in many parts of the prison, but the trouble continues. Those in charge soon learn to give as little heed as possible to his many inventions. The notes of one overseer show his impression; he wrote: "This prisoner is an awful liar; . . . said he saw two convicts trying to cut through their door; . . . said another prisoner was going to stab him with a pair of shears; . . . he is a professional at lying and I have seen many bad prisoners but never one like this man." A frequent charge made by Francis had been that cell-mates have secreted in their cells substances that are contraband, such as coffee, cocoa, sugar and money.

Once, with grave concern, the convict reported that he saw another inmates hide tools in the sewer preparatory to an attempt at escape; on investigation, it was found that the cover of the sewer, which the prisoner said he had seen removed, was securely cemented and had been so for years; it was but another myth.

At a former examination he stated that he had knowledge of seven languages—Russian, Lithuanian, Polish, Finnish, German, French and English. When shown French he failed to recognize it, and when told to write that language he wrote what appeared to be some Slavish dialect, which he explained was called French where he had studied.

If questioned concerning his fabrications, he attempts to pass the subject off lightly; but when pressed for an explanation he has said: "I was bluffing"; that "others have lied to

me first"; that "often I have lied to defend or to protect myself, which I considered a justifiable fraud"; and that "sometimes I have lied to develop a situation about which I was suspicious."

The prison classification of this man is a criminal of the homicidal type. The further mental classification is psychopathic personality. Outstanding features are: emotional instability; abnormal sexuality; pathologic lying; possibly, still suicidal. Neurologic findings are: paralysis of part of the right facial nerve; bullet in the left temporal lobe of the brain, probably nonsymptomatic.

A CASE OF INCARCERATED HERNIA INTO THE UMBILICAL CORD

WILLIAM J. STANTON, M.D., WASHINGTON, D. C.

M. T. H., a girl baby, born, Dec. 22, 1919, and weighing 8 pounds, presented a large tumor mass about the size of a fist, within the umbilical cord. Transillumination revealed coils of intestine. A diagnosis of hernia into the umbilical cord was made, and immediate operation was advised. This was at first refused, but next day the parents consented, and the baby was sent to Georgetown University Hospital, where I operated, just twenty-four hours after I had delivered her. Dr. Thomas F. Lowe administered the anesthetic.

The wall of the sac consisted of amnion and peritoneum. The sac contained about 2 feet of large and small intestine. The appendix, though present, was not removed. The intestine was adherent over about half the surface of the sac. The intestine was beginning to show a dark reddish discoloration.

An incision of the umbilical ring and abdominal wall above the cord was made. The intestine was replaced and the wound closed with three silkworm-gut inverted mattress sutures. The baby suffered little if any shock, and made an uneventful recovery. The after-treatment consisted in a regular four-hour nursing schedule. The baby was returned to her mother the same night.

THE EFFECT OF WEAK ACETIC ACID ON SPIROCHAETA PALLIDA

PRELIMINARY COMMUNICATION

HERMAN GOODMAN, B.S., M.D., NEW YORK

I wish at this time to give the clinical and experimental evidence as to the effect of weak acetic acid on *Spirochaeta pallida*, in order that corroborative work may be carried on.

It is generally admitted that syphilitic chancres of the vagina are less frequent than chancres of the neighboring parts. Most textbooks make the statement, and the figures are easily available. It is also generally admitted that the secretion of the vagina of the adult woman is acid. The secretion of the adjacent parts is alkaline in reaction. Certainly the vagina is equally subject to trauma and to the deposition of *Spirochaeta pallida*, as the cervix uteri or the labia, the usual sites of chancre on the female genitals.

In the few reports of chancres of the vagina which give the exact location of the initial lesion, it is most often in the posterior culdesac. The alkaline cervix uteri secretion which may collect here is the factor in the neutralization of the protective acid vaginal secretion.

The immunity that the vagina apparently has for syphilitic manifestations has been commented on in the past, as has its comparative immunity to chancroids and to the gonococcus.

With the object of determining the action of weak acetic acid on *Spirochaeta pallida* prior to using this solution to hemolyze blood in attempting to recover *Spirochaeta pallida* in samples of circulating blood, I noted the following: As opportunities presented themselves, spirochetes were sought for under the dark field. When found, acetic

acid prepared from chemically pure glacial acetic acid diluted to 2, 1 and 0.5 per cent. with distilled water was run under the cover glass of different preparations of fresh spirochetes. Currents were of course set up, which caused a general movement of the material under observation. However, as soon as I could recognize objects again (within fifteen seconds), it appeared that the spirochetes were much changed. They had lost the regularity of coil, they were no longer straight, they were immotile, and they were carried passively on the currents. The effect was much like that described by Reasoner¹ for soap solution.

It may be noted that the mediums for the growth of spirochetes must be alkaline.

I was led to believe that *Spirochaeta pallida* is unable to live in an acid environment even as low as 0.5 per cent. acetic acid. It would appear, then, that an acid solution, such as weak acetic acid, may be of use in the prophylaxis of syphilis. The advantages of a nonpoisonous, liquid, easily procurable and adaptable local spirocheticide should warrant a serious study. It is proposed to carry on this investigation with animal inoculation, and also to determine whether acetic acid penetrates farther into tissues such as the skin or mucous membranes than solutions of other known local spirocheticides.²

LAXATIVE FRUIT CAKE

DR. EDWARD J. ROGERS, Pittsford, Vt., writes: "In your issue of Dec. 27, 1919, p. 1938, you speak of 'senna leaves, figs, dates, prunes, raisins—of each, equal parts.' Does this mean by weight or measure?"

COMMENT.—Since the dose of this "laxative fruit cake" is a slice, large or small, according to the requirements of the individual, exact proportioning of ingredients is not essential. Either weight or measure might be used; the former, being more accurate, would be preferred.

Meningitic Form of Acute Poliomyelitis.—Every doctor realizes that the great fear at the back of his mind is tubercular meningitis. No disease is so deceptive, and the clinician has hardly a sure test by which he can guide his diagnosis, because the onset, though gradual, as a rule, may be as abrupt as in cerebrospinal meningitis, and any of the cardinal signs may be in abeyance. Examination of the cerebrospinal fluid may settle the diagnosis, but even this, in the absence of tubercle bacilli, may not be conclusive, because in this form of poliomyelitis the character of the fluid varies considerably. When taken early there is, as a rule, an increased cell count with a low globulin content, and the cell increase is in the lymphocytes and large mononuclear cells. In some cases, however, the polynuclear cells predominate. The absence of tubercle bacilli, of meningococci and other bacteria, will certainly suggest the possibility of poliomyelitis, and then the clinical signs will probably lead to the right conclusion.—*Clinical Journal*, December, 1919.

NUTRITIVE REQUIREMENTS BASED ON ACCURATE STATISTICAL EVIDENCE

Few questions relating to nutrition and the bearing of the diet on human well-being have aroused more discussion in the last few years than has the subject of the protein requirement of man. Extremes of opinion have been advocated with much vigor. The assumed menace of a diet rich in protein has been pictured in the form of various nutritive dangers, such as the ills of the indefinable "autointoxication," the hypothetic "kidney overwork," arteriosclerosis and arterial hypertension developed by a surplus of nitrogenous waste products, and other equally indefinite factors. Instances of alleged benefit from reduction in the protein intake are often cited to substantiate the statements. Somewhat less aggressive, though by no means wanting in enthusiasm, are the counter claims of those who believe that the welfare of the race is bound up with liberality in the protein factor. Pointing to the parallel occurrence of low protein dietaries and undersized races, the advocates of abundant nitrogenous intake look on protein as a veritable stimulus to growth, vigor and even happiness. "Underfeeding produces gloom and moroseness unless other circumstances are more influential and oppose it." Such are some of the dicta of the opposing extremists.

The medical man is, or ought to be, sufficiently familiar with human psychology to appreciate the element of bias in many of the propagandas relating to health. At one time, not many months ago, the experience of the Germans with the enforced low-protein dietary of war time was proclaimed as clear cut evidence of the safety and, in cases, even the benefit of such a regimen. Later, when disease undoubtedly attributable to improper nutrition began to make its appearance in many places, the interpretations began to swing in a different direction with respect to the need of protein. The blame for many of the ills was now laid at the door of the inadequate supply of this foodstuff. As a matter of fact, so many variables are concerned in the malnutrition of central Europe—the inadequate calorific intake, the inappropriate and extremely limited variety of food, with a consequent

reduction of quantity and defect of quality, including perhaps vitamin and mineral nutrients as well as the energy-yielding foods—that a rational interpretation of the causes is by no means easy in all cases. Otherwise the diversity of phenomena represented by beriberi, rickets, scurvy, war edema and pellagra might readily be ascribed to a single cause, such as low protein or inadequate calories.

There is something singularly satisfying in evidence that is essentially objective in character and does not require the consideration of the psychologic or human factor of interpretation. For this reason, well controlled experimental data from intelligently conceived investigations are always welcomed in the study of nutrition. In connection with the protein requirement of man, Sherman¹ of Columbia University has completed the desirable task of compiling the dependable statistics of the observations in which the protein intake appears to have been barely sufficient or not quite sufficient to result in equilibrium of intake and output, provided the total diet was adequate. Such figures must approximate the minimum requirement. This will, of course, necessarily vary with the character of the diet and certain other factors; but, on the whole, variations due to these must be offset to a considerable degree when the number of observations is large. Sixty-seven experiments on men show an average "indicated protein requirement" of 0.633 gm. per kilogram, while the forty-two experiments with women average 0.637 gm. per kilogram of body weight. It seems unnecessary, therefore, to distinguish between the sexes in this discussion since we are dealing with data calculated to a uniform basis of body weight. The general average of the 109 experiments shows an indicated requirement of 0.635 gm. of protein per kilogram of body weight, or 44.4 gm. for the "average man" of 70 kg., daily.

Such conclusions drawn from an unusually large number of observations, in which the personal equation of interpretation has been minimized, must not be regarded as representing the index for optimal protein intake; on the contrary, they must be looked on as the rock bottom or irreducible minimum in all considerations of adequate rationing, particularly when large groups of persons are to be provided for.

A similar survey made by Sherman² with respect to the phosphorus requirement of man deserves notice in this connection. The data from ninety-five experiments range from a minimum of 0.52 to a maximum of 1.20 gm., with an average of 0.88 gm. of phosphorus per 70 kg. of body weight daily. The experiments on men average 0.87 gm., and those on women average 0.89 gm. per 70 kg. daily. Sherman believes that we are probably justified in concluding that we now know

2. Sherman, H. C.: Phosphorus Requirement of Maintenance in Man, *J. Biol. Chem.* **41**:173 (Feb.) 1920.

the phosphorus requirement with about the same probable accuracy that the protein requirement is known, and that about one-fortieth to one-fiftieth as much phosphorus (reckoned as element) as of protein is required in the maintenance metabolism of man. Such investigations of the dietaries of typical American households indicate that with few exceptions they appear to provide a somewhat more liberal margin of protein than of phosphorus. Nevertheless, the minimum requirement of the latter is apparently rarely approached. At any rate, as the conventional diet supplies phosphorus in forms entirely suitable for utilization by man, there is no ground for any commercial exploitation of unique types of phosphorus compounds that exhibit little advantage other than that of a large monetary return to a persistent promoter.

THE PHYSIOLOGIC SIGNIFICANCE OF A RECORD AEROPLANE FLIGHT

A few days ago an aeroplane carrying Major R. W. Schroeder of the American army aviation service reached an altitude of 36,020 feet, about 5,000 feet higher than the previous world's record for such a mode of flight. Only a few years ago this marvelous performance would have been rated as virtually impossible because of the limitations of the human organism at great heights. In the oft quoted balloon ascension of the meteorologist Glaisher, in 1862, an altitude of about 30,000 feet was reached. When the balloonist attained a height of 26,000 feet, he first noticed that he could not read his instruments properly. Shortly after this his legs became paralyzed, and then his arms, though he could still move his head. Then his sight failed entirely, afterward his hearing, and he became unconscious. Glaisher's companion, Coxwell, likewise incapacitated in the upper air, managed to open a valve which permitted the balloon to descend, and thus saved the lives of the men. Another historic instance of a record balloon ascension concerns the experience of Tissandier, the sole survivor of a party of three in the fatal trip of 1875. The balloon ascended 28,820 feet, but all the occupants of the car began to suffer before an altitude of 23,000 feet was reached, and two of them died.

The baneful effects on life in the rarefied air of higher altitudes usually makes itself manifest at a barometric pressure considerably lower than that represented in the classic instances just cited. In a review of the medical aspects of aviation, the experts of the Medical Research Laboratory of the Division of Military Aeronautics¹ assert that mountain sickness befalls some persons at a lower, others at a higher altitude; but it is also certain that no one who proceeds beyond a certain elevation—the critical line for him—escapes the malady. An elevation of 10,000 feet or even less

might provoke it in some; others may escape the symptoms up to 14,000 feet, while only a very few, possessed of unusual resisting power, can without much distress venture upward to 19,000 feet. We are further reminded that the symptoms of mountain sickness depend not only on the nature of the individual and his physical condition, but also on various intricate contingencies, especially on the amount of physical exertion made in ascending; that is, on whether the ascent is performed by climbing or by passive carriage on horse, on railway train, or in an aeroplane.

What has made possible the penetration of the higher reaches of the atmosphere in these newer flights of man, including Rohlf's ascent to 31,000 feet and Casale's unofficial record of 33,000 feet last year, and culminating in the splendid achievement of Schroeder in rising nearly seven miles above the earth? It has been the scientific demonstration that the predominant physiologic upset at high altitudes, whether it be exhibited as mountain sickness (*mal des montagnes*) or aviator's disease (*mal des aviateurs*) is primarily due to the deprivation of oxygen in the rarefied air. As long ago as 1878 the eminent French physiologist Paul Bert furnished clear experimental proof that the abnormal symptoms and dangers experienced under conditions of lowered barometric pressure are those of want of oxygen. Despite the various attempts to invoke other factors, the accumulated scientific evidence today supports Bert's conclusion that the essential cause of altitude sickness is lack of oxygen. Consequently, he who would attempt the conquest of the air several miles above the earth must be supplied with oxygen in sufficient abundance.

The adaptation of man to life at altitudes has occasionally been discussed in *THE JOURNAL*.² Important as they undoubtedly are for the mountaineer and, latterly, for the aviator under ordinary circumstances of flying, these adaptive responses cannot satisfy the needs of the organism in those record flights represented by Schroeder's attainment. Accordingly, it is significant that his failure to ascend even higher in the world's record flight was due, according to the press dispatches, to the exhaustion of the aviator's oxygen tanks which supplied the needed respiratory gas. It is this failure, we may assume, in the absence of official information, which robbed him of consciousness and thus was responsible for the spectacular fall of several thousand feet which almost cost Schroeder his life.

The glowing accounts of the new conquest of the upper air have been replete with praises of the superior motors, the dependable air compressors, the unique recording instruments, the heating devices that made it possible for man to endure a polar climate of 67 degrees below zero, and other mechanical features. It is more than likely that the record will again be broken:

2. A New Record for Altitude, editorial, *J. A. M. A.* 72:496 (Feb. 15) 1919; The Medical Manual of the Air Service, *ibid.* 72:1368 (May 10) 1919; Deaths Incident to Aviation, *ibid.* 73:1444 (Nov. 8) 1919.

1. Manual of Medical Research Laboratory, War Department, Air Service, Division of Military Aeronautics, Washington, 1918, p. 8.

not, however, merely because these devices have been made more perfect and efficient, but also because science will have taught the aviator how to secure an unfailing supply of the indispensable oxygen. After the enforced consideration during the last few years of the abomination of noxious gases, it is a relief to return to the consideration of one that is truly beneficent.

APPLICATIONS OF CLINICAL CALORIMETRY

Several years ago (May, 1915), the *Archives of Internal Medicine* devoted a supplementary number solely to the presentation of pioneer results obtained by the method of clinical calorimetry. To some the subject seemed at that time to be far removed from any immediate application to the problems of medical practice. The technic of the investigations involved highly specialized training; the language in which some of the results were expressed had a novel and unfamiliar ring; and "basal metabolism" seemed at most a topic for the consideration of the trained physiologist and the pathologist.

In the few intervening years, the technic and the necessary apparatus for estimating the energy exchange in human subjects have been simplified so that they are no longer beyond the capacities of intelligent clinicians. To the uninitiated the methods sound more complex than they really are. They are not among the easiest of routine diagnostic procedures; neither is good surgery the work of a tyro; yet we do not relegate it to some superhuman person.

Recently the clinical importance of an estimation of basal metabolism in thyroid disease as an index of the toxicity factor has repeatedly been emphasized.¹ As McCaskey has pointed out, the differential diagnosis of many mild, atypical or very early cases of thyrotoxicosis by means of the ordinary clinical signs and symptoms can be made with only a varying degree of probability. The estimation of the basal metabolism furnishes the requisite objective data which verify a diagnosis and enable one to gage the value of therapeutic efforts. An excellent illustration is afforded by the studies of the basal metabolism in exophthalmic goiter which were started by Means and Aub² at the Massachusetts General Hospital nearly five years ago. It has been possible to contrast the more permanent effects of a variety of modes of treatment in a disease characterized by a high metabolism rate. Judging by this index of toxicity, it now appears that in the majority of cases the results after two or three years are equally as good with roentgen-ray treatment as

with surgery. In securing the same end-results with surgery or with the roentgen ray, a lesser rest factor is necessary with the roentgen ray. With the roentgen ray there is practically no mortality. With surgery there is a definite one. Patients treated surgically do better, and the risk of operation is less, if they have previously had their thyroid and thymus glands irradiated. The risk of operation is greater and the need for preoperative roentgen-ray treatment is greater in cases with a very high metabolism and moderate tachycardia and moderate metabolism elevation.

From their studies with the aid of the respiration calorimeter, Means and Aub believe that the safest program for the treatment of exophthalmic goiter, as a whole, is the routine irradiation of thyroid and thymus glands, in all cases, with surgery held in reserve for patients who do not then do well. The Boston diagnosticians conclude that surgery is contraindicated with patients whose metabolism is rising in spite of complete rest in bed, and also patients of the type with moderate tachycardia and great metabolism increase, except when they have previously had the thyroid and thymus glands treated with the roentgen ray. If one is justified in asserting today that "in the management of exophthalmic goiter, periodic determination of the basal metabolism should be quite as much a routine as is the examination of the urine for sugar in diabetes mellitus," it must be admitted that clinical calorimetry has won a place for itself within an unexpectedly short period.

THE PATHS BY WHICH TETANUS TOXIN AND ANTITOXIN ARE SPREAD IN THE BODY

It has long been recognized that tetanus poison has a special affinity for the nervous system. More than twenty-five years ago, Bruschettini¹ demonstrated that the toxin might be found in the nerves but not in the adjacent muscles and other tissues surrounding the point of subcutaneous injection. It is to Meyer and Ransome,² however, that medical science owes the complete proof that the tetanus poison is absorbed from the blood and tissues by the peripheral nerves and transported centrally along their paths. For example, when tetanus toxin is injected into the thigh muscles of an experimental animal, the poison is found at first only in the sciatic nerve of the same side and in the blood.

The process by which this transport of the tetanus toxins occurs has been widely discussed. For some time it was believed that the lipoids, which are conspicuously abundant in nervous tissues, are responsible for the selective transfer of the toxin. These com-

2. Meyer and Ransome: Arch. f. exper. Path. u. Pharmacol. **49**: 367, 1903.

pounds, like the fats, are known to have a specially marked solubility for certain types of compounds, notably some of the narcotic drugs. It was not unnatural, therefore, to assume some sort of chemical or physical affinity between the toxin and the lipoids of the nervous structures. The problems here at issue have more than merely academic interest, for the possibility of successful therapy largely depends on the solubility and mode of distribution of toxin and antitoxin in the tissues and fluids of the body. No amount of antitoxic substance, however large, and however potent it may be *in vitro*, will be effective if it cannot reach the *materies morbi* in the body itself. Obviously, if the nerves themselves offer a better point of therapeutic attack, antiserum might be injected more directly in the vicinity of the poison to be neutralized.

In the classic investigations on the action of tetanus toxin, it was found that when a nerve is cut, poison absorption ceases as soon as axis cylinder degeneration has set in. Meyer and Ransome concluded that tetanus toxin reaches the central nervous system solely by way of the axis cylinder of the motor nerves. Marie and Morax³ had come to a similar conclusion. A reinvestigation of the problem at University College Hospital Medical School in London by Teale and Embleton⁴ has emphasized the possible cooperation of other factors in the distribution of tetanus toxin. Their experiments show that although the poison ascends to the central nervous system by way of the axis cylinders of the nerves, it also to a great extent passes up the nerves to the cord by way of the perineural lymphatics. Blocking the latter paths greatly delays, and in some cases completely prevents, the occurrence of tetanus in the part corresponding to the nerve for which the lymph path has been blocked. Although tetanus toxin passes rapidly from the blood vessels into the connective tissue spaces and thence to the thoracic duct, the toxin does not pass from the capillaries of the central nervous system to its tissues.

The British investigators feel justified, further, in concluding that tetanus antitoxin is not carried in any degree to the cord either by the axis cylinders or by the neural lymphatics when inoculated directly into the nerve, but that its sole action when thus introduced appears to be the local neutralization of the toxin coming up the neural lymphatic sheaths. According to Teale and Embleton, this appears to be further evidence that tetanus toxin travels in the neural lymphatic sheaths; hence they conclude that antitoxin acts on the toxin in the circulation and tissues, and prevents its spread from there into the nerves and central nervous system, and that it has no effect on the toxin already traveling along the nerve or present in the central nervous system.

THE NEW ORLEANS SESSION

The American Medical Association will hold its seventy-first annual session in New Orleans, April 26 to 30. A description of the features of the session and the preliminary programs appear in this issue. This is the fourth time the Association has convened in New Orleans. The twentieth annual session under the presidency of Dr. William Owen Baldwin in 1869 aided much in bringing the members of the medical profession in the South into cordial relationship with the national association following the Civil War. Then, in 1885, under the presidency of Dr. Henry F. Campbell, the thirty-sixth annual session was held in the Crescent City. In 1903, for the third time the Association met in New Orleans in its fifty-fourth annual session under the presidency of Dr. Frank Billings. Now we are to enjoy New Orleans hospitality for the fourth time; on this occasion the session will be opened under the presidency of Dr. Alexander Lambert of New York, and Dr. William C. Braisted, Surgeon-General of the U. S. Navy, will be inducted into the office of President. The physicians of New Orleans propose to maintain the reputation of their city for hospitality. They are resolved that the Fellows of the Association who attend the coming annual session will not only enjoy the program of the Scientific Assembly, but will also find every moment intervening between the scientific meetings fully occupied with social features which shall mark this annual session as providing an all-around good time socially. While the hotels of themselves may not be able to accommodate all those who will be in New Orleans, the Local Committee on Arrangements has undertaken and is accomplishing the Herculean task of assuring every visitor comfortable lodgings during the time of the meeting. Not only has there been provided a list of approved boarding houses, but the physicians themselves as well as other citizens of New Orleans, are opening their homes for the accommodation of the visiting profession. New Orleans is proud of the hospitality it extends to visitors who attend the Mardi Gras, and a like welcome awaits every one at the coming session of the Association.

THE SANITARY CONSCIENCE

In that superb series of essays which was to honor Osler in the life, but which his eyes never beheld and which is now lamentably enough a memorial to the great physician, Sir Auckland Geddes, the new ambassador of Great Britain to the United States, deplors that physicians in general lack the spirit of citizenship: They are unwilling, he says, to share governmental burdens; they feel but little of that mass emotion which is concerned for physical and mental development, for closer human relationship, and which is finding expression "in centers for child welfare, in schemes for housing the working classes, in the establishment of ministries of health, in reconstruction and research work, in the growth of the labor party, in the spread of socialism and, incongruous though it may seem, in

bolshevism and in the great ideal struggle to express itself through the League of Nations." With "brilliant exceptions," the medical profession, Geddes considers, is made up of men whose citizenship, such as it is, "is as divorced from their technical knowledge as is that of the speculator when he jerry-builds new slums."¹ Surely there is here no stricture as to the medical profession in the United States, which, in the last decade at least, has shown itself so zealous in the communal interest. Consider a few data in point: The medical profession several years ago sought most earnestly and with no selfish motive for the establishment of a national department of public health, with representation in the President's cabinet. This movement, promising so much nationwide beneficence, was frustrated through the efforts of agencies which can hardly be said to have been saturated with zeal for the welfare of our people. Also, there is even the insistence, by the informed physician, on the fact that tuberculosis is far from being only a doctor's affair, but that it is probably the most degenerating social and economic factor in civilization. Many, no doubt most medical societies, have their public health sections or committees in which the application of twentieth-century preventive measures to the correction of untoward communal conditions has been thoroughly promulgated, in which factory insanitation, woman and child labor, impure air and water, and a thousand and one other aspects of general unhealthfulness are exhaustively considered. There does, indeed, appear to be in our body politic some indication of an upsurging "mass emotion" making for human physical and mental betterment. Rosenau of Harvard has better characterized this salutary and promising emotion as an awakening sanitary conscience among our people. "The modern science of preventive medicine," he has said, "teaches the lesson of the unselfishness of community interest and has been a potent biological factor underlying the present trend toward socialism." Such teaching, by physicians interested in the larger aspects of medical science, is now in the way of bearing fruit.

1. Geddes, Sir Auckland: Social Reconstruction and the Medical Profession, Contributions to Medical and Biological Research, Dedicated to Sir William Osler, in Honor of His Seventieth Birthday, by His Pupils and Co-Workers, July 12, 1919, p. 70.

Child Labor and the War.—The seventh annual report of the chief of the Children's Bureau of the U. S. Department of Labor points out that the federal child labor law which had gone into effect, Sept. 1, 1917, prohibited the employment of children under 16 years of age in mines and quarries and of children under 14 years of age in factories; limited the working day to eight hours for children under 16 years of age employed in factories, and prohibited work for them between 6 p. m. and 7 a. m. But this law was declared unconstitutional by the supreme court, June 3, 1918. The immediate effect of the supreme court decision in states where the state child labor standards were lower than those imposed by the federal law was the prompt restoration of the longer working day for children under 16 and an increase in the number of working children. In a number of states there was an appreciable increase in the violation of state laws. It was in recognition of the seriousness of this increasing employment of young children that the war labor policies board voted that compliance with the standards of the former federal child labor law should be required of establishments engaged on government war contracts made after the date of the decision.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

DISTRICT OF COLUMBIA

Personal.—Dr. Marcus W. Lyon, Jr., has taken charge of the pathologic work at South Bend, Ind.

Bill on Chiropractic.—There has been introduced by Congressman Esch a bill regulating the practice of chiropractic in the District of Columbia. This measure is similar to the one recently introduced relative to the practice of osteopathy in the district. It provides for the organization of a chiropractic examination and registration board; that applicants for chiropractic licenses shall be graduates of reputable schools of chiropractic, that the applicants will be required to give a demonstration of vertebral palpation, nerve tracing and adjusting, and such other subjects as the board may prescribe. A fee of \$25 is required of all applicants seeking licenses. A renewal fee of \$5 each year is required.

FLORIDA

Kansas City Physician in Florida.—Dr. Richard L. Sutton, Kansas City, Mo., was the guest of Dade County Medical Society at Miami, February 25, and delivered an address on "Cancer of the Skin," illustrated by lantern slides.

Personal.—Dr. John Keeley, health officer of the East Coast Congressional District, has resigned.—Dr. Daniel C. Campbell, Jacksonville, has been appointed head of the bureau of venereal diseases, succeeding Dr. Lorin A. Greene, Gainesville, resigned.

Public Health Service Takes Lake City Property.—The Columbia College property, Lake City, was taken over March 1, by Dr. Goff, U. S. P. H. S. The work of renovating and remodeling is to be pushed ahead as rapidly as possible. The hospital will be operated directly under the Bureau of War Risk Insurance.

GEORGIA

Ellis Law Adopted.—Decatur County has adopted the Ellis health law and will begin operating with a full-time commissioner of health very shortly. Decatur is the seventeenth county to adopt this law.

Judgment Against Physician.—The damage suit brought by Mrs. Marie W. Whitman against Dr. William B. Crawford, Savannah, in which \$20,000 damages were claimed, is said to have been decided in favor of the plaintiff, January 28, a jury awarding her damages of \$2,000.

Free Clinic.—The Chamber of Commerce of the city of Fitzgerald held a special meeting, at which the members of the Ben Hill County Medical Society were guests, in an endeavor to organize against vice and venereal diseases. The meeting was addressed by Dr. Josephus P. J. Bowdoin, Adairsville, director of the venereal disease control department of the state board of health. As a result of the meeting a free clinic will be organized in Fitzgerald.

ILLINOIS

Physician Arrested for Sedition.—Dr. Oscar J. Brown, DeKalb, leader of radicalism in his section of the state, is said to have been indicted by a special grand jury, March 9, charged with violation of the Illinois sedition act.

Physician's License Revoked.—Monday, March 1, 1920, the Department of Registration and Education revoked the license of Dr. Warren D. Scott, Decatur, on the ground that he had been conducting offices in different parts of the country under the name "United Doctors."

Personal.—Dr. Frederick H. Lamb, Davenport, Iowa, has been appointed pathologist to St. Anthony's Hospital, Rock Island.—Dr. Edmund Summers, Mattoon, while driving his automobile across the tracks of the Illinois Central Railroad near Mattoon, February 27, was struck by a train and seriously injured. He is under treatment in the Mattoon Hospital.

Public Nurses Provided.—As a result of a recent conference between Dr. C. St. Clair Drake, Springfield, state director

of public health, and Miss Helen Fox, Washington, superintendent of the public health nursing service of the American Red Cross, every community in Illinois of more than 5,000 population will be provided with a community nurse. Miss Etta Lee Gowdy was chosen supervising nurse for the state, and Miss Minnie Ahrens for the Chicago district.

Chicago

Honor Dr. Gilmer.—The Chicago Dental Society will give a dinner in honor of Dr. Thomas Lewis Gilmer, March 23, in the gold room of the Congress Hotel.

Physician Arrested for Sedition.—Dr. Karl F. M. Sandberg is said to have been indicted by a special grand jury, March 9, charged with violation of the Illinois sedition act.

Physician Fined.—Dr. Alois C. Rasmussen is said to have been fined \$100 and costs by a police magistrate in Oak Park for failure to report a case of scarlet fever to the health commissioner of that village.

Personal.—Dr. Hugh N. MacKechnie has resigned from the medical department of Loyola University.—Dr. Effie L. Lobdell has been appointed professor of obstetrics in the Illinois Post-Graduate Medical School.

Dr. Wile in Chicago.—An informal dinner in honor of Dr. Udo J. Wile, Ann Arbor, was given at the University Club, March 17. After the dinner Dr. Wile presented a paper before the Chicago Medical Society on "A Critical Study of Two Obscure Phases of Hepatic Syphilis."

Effect of Prohibition.—It is announced that the Washingtonian Home closed its doors, March 15, and moved to much smaller quarters at the Martha Washington Home on Irving Park Boulevard. The home was founded in 1863, and since that time has cared for 50,000 liquor and drug addicts.

Research Club Meeting.—The Medical Research Club of the University of Illinois held its fifty-second meeting, March 12, at the City Club. Prof. Louis Kahlenberg of the University of Wisconsin detailed "The Result of Experiments in the Passage of Substance Through the Skin by Osmosis," and Dr. Edward H. Ochsner spoke on "Osmosis in Relation to Clinical Medicine."

Medical School Changes Name.—Aug. 1, 1919, legal authority was granted to the Chicago Hospital College of Medicine, an institution rated as Class "C" by the Council on Medical Education, to change its name to the Chicago Medical School. The certificate filed in the office of the Secretary of State of Illinois, Feb. 5, 1915, grants this college authority for

"Education and general contracting, including the operation of hospitals, sanitariums, laboratories, preparatory and professional schools and the conferring of the degrees of Bachelor, Master and Doctor of Sciences, Arts, Laws, Medicine, Surgery, Public Health, etc."

INDIANA

County Hospital Favored.—At the city session, March 9, the residents of Blackford County voted for the erection of a county hospital to cost \$80,000. The proposal won by a majority of 782, the total votes cast being 2,262.

Deaths in Indiana.—The registrar-statistician of the state board of health reports that there were 9,184 fewer deaths in the state in 1919 than in 1918, the respective figures being 37,077 and 46,261. There was also a decline of 5,623 in births in 1919, as compared with the previous year, the respective figures being 58,690 and 64,313.

Personal.—Dr. George S. Bliss, Fort Wayne, superintendent of the state school for the feeble-minded has resigned to accept the position of superintendent of the school for feeble-minded of Honolulu, Hawaii, and Dr. Melvin Druckmiller has been appointed acting superintendent.—Dr. Charles G. Beall has been appointed a member of the medical corps of the institution.—Dr. Osborne T. Brazelton, Princeton, while returning with his family in his car from Patoka, January 29, was shot at, the bullet crashed through the windshield of his car and he suffered a number of slight wounds of the face.—Dr. Alembert W. Brayton, Indianapolis, celebrated his seventieth birthday anniversary, March 3.—Dr. George W. Frederick, Kokomo, was operated on at the Good Samaritan Hospital, Kokomo, February 24, for the removal of gallstones.

MARYLAND

Personal.—Dr. Allen W. Freeman, Columbus, commissioner of health for Ohio, lectured on the public health administration of Ohio, March 8, at the School of Hygiene and

Public Health, Johns Hopkins University.—Dr. Edgar M. Parlett, Baltimore, formerly supervisor of sanitation in the relief department of the Baltimore and Ohio Railroad at Baltimore, has been appointed manager of the health and sanitation bureau of the Carnegie Steel Company, with headquarters at Pittsburgh.—Dr. William S. Halsted, Baltimore, has been elected to honorary foreign membership in the Royal Academy of Medicine, Belgium.

Colleagues Honor Professor Welch.—In April Dr. W. H. Welch reaches his seventieth birthday. As a recognition of this event, his friends have determined to preserve in suitable form the chief contributions of Dr. Welch to medical literature. They have been brought together for publication in three volumes. Friends and former pupils of Dr. Welch are invited to subscribe. The volumes will be issued by the Johns Hopkins press under the editorial supervision of a representative committee. The three volumes, bound in linen, are offered to subscribers at \$16.50. Copies, which will be numbered and assigned in order of subscription, may be secured by addressing the press.

MASSACHUSETTS

Personal.—Dr. Michael F. Burke, Natick, sustained serious injuries of the head and back when his sleigh was struck by a Boston and Worcester street railway car in Natick, February 9.—Dr. Frederick R. Barnes, Fall River, has been appointed associate medical examiner (coroner) for the Third Bristol District, succeeding Dr. John H. Gifford, deceased.

MICHIGAN

Medical Building for Flint.—Twenty-five physicians and dentists of Flint have incorporated the Flint Medical Association with a capital stock of \$50,000, the purpose of which is to erect a six story building to be devoted exclusively to professional purposes.

Personal.—Members of the Pontiac Medical Club, February 25, gave a dinner in honor of Dr. Joseph G. Knapp, former secretary of the club who is moving to Cleveland, and presented him with a leather traveling case. Dr. Carlton D. Morris, Pontiac, was selected president; Dr. John W. Fox, Pontiac, vice president, and Dr. Harry B. Yoh, Pontiac, secretary.—Dr. Vilda S. Laurin has been appointed acting city physician of Muskegon, succeeding Reuben J. Harrington.

The Care of Children's Teeth.—The Genesee County Medical Society, at a recent meeting in Flint, adopted a resolution agreeing to take every opportunity to instruct those coming under the care of the members with reference to the need of beginning the care of the teeth of their children at 2½ or 3 years of age, or as soon as erupted; agreeing to give all children coming under their care competent and conscientious attention; endorsing the start made by the dental division of the health department of Flint, in the establishment of free dental clinics; recommending the extension of this work, and the need of competent care with more frequent examinations, and advice as to matters which cannot readily be made practical in the public dental clinic. The dental division of the department of health now has three full-time dentists and one dental hygienist. The aim of the department is to build it up, so that free dental care may be given to all children whose parents wish to take advantage of it.

MISSISSIPPI

Funds Provided for Malarial Survey.—The city council of Columbus, February 17, made an appropriation of \$3,000 for carrying out a malarial survey.

Colony for Epileptics.—The state senate, February 25, passed a bill for founding, equipping, and conducting a state institution or colony for the feeble-minded and epileptics.

State Board Meeting.—At the annual meeting for organization of the state board of health held in Jackson, February 27, Dr. J. Harvey McNeill, Olive Branch, was elected president of the board, and Dr. Waller S. Leathers, University, was reelected secretary and executive officer.

New Hospital Building for Soldier's Home.—The delegation from the state legislature which visited the Jefferson Davis Soldiers' Home, Beauvoir, February 28, expressed themselves as being in favor of providing the home with a new hospital, the present structure being regarded as inadequate and unsafe. It is proposed to erect a new brick hospital to cost \$125,000.

Personal.—Dr. John A. Mead, Logtown, has been appointed health officer of Hancock County, to succeed Dr. Joseph W. Moody, Kiln, resigned.—Dr. George Y. Hicks, Vicksburg, has been appointed superintendent of the State Charity Hospital, Vicksburg.—Dr. James O. Ringold has been elected health officer of Montgomery County.—Dr. James A. Toole, Marks, has been elected health officer of Quitman County.—Dr. William I. Marsalis, Centerville, has been elected health officer of Wilkinson County.

NEW MEXICO

Personal.—Walter M. Connell, chairman of the city commissioners of Albuquerque, has been appointed first vice president of the New Mexico Public Health Association to fill the vacancy caused by the death of Dr. Oliver T. Hyde.—Dr. Frank N. Carrier, Santa Rita, has been elected secretary, and David R. Boyd, treasurer, of the New Mexico Public Health Association.—Dr. Le Roy S. Peters, Albuquerque, has been appointed medical director of St. Joseph's Hospital, succeeding Dr. Oliver T. Hyde, deceased. Dr. Arno Klein, Albuquerque, has been appointed assistant medical director of the hospital.

New Health Law.—Senate bill No. 5, which passed the senate with a vote of seventeen to five and the house of representatives unanimously and was signed by the governor, March 1, provides that, whenever in the opinion of the commissioner of health, conditions require the employment of persons in addition to county and city health officers to carry out the health laws, rules and regulations, these may be employed by the governing boards of counties and incorporated municipalities. To provide for the current expenses of the health department, boards of county commissioners are authorized to levy a tax not to exceed one-half mill on each dollar of taxable property in the county, exclusive of that within incorporated municipalities. The governing bodies of such municipalities may levy a tax not exceeding one-half mill on each dollar of taxable property within their boundaries.

NEW YORK

Personal.—Dr. William L. Munson, Granville, sanitary supervisor who was taken ill with pneumonia while in Plattsburg in connection with the public health course for nurses at the Champlain Valley Hospital, is convalescent and has returned home.

Civil Service Examinations.—The state civil service commission announces that examinations will be held, April 10, for the positions of bacteriologist-pathologist, state department of health, with a salary of \$2,500 to \$3,000; laboratory assistant and bacteriologist, state department of health, with a salary of \$900 to \$1,320, and laboratory apprentice, state department of health, with a salary of \$840.

Beneficiaries of Dr. John Van Der Poel's Will.—The will of Dr. John Van der Poel, who died, February 23, disposes of an estate of more than \$200,000, and many family heirlooms, one of which is "an old English pepper grinder," which had been in the family many generations, and which is bequeathed to his attorney Edward R. Boise. A painting on wood by Egbert Van der Poel, dated 1640, and Rembrandt's "Lessons in Anatomy" go to the Albany Institute and Historical Society.

New York City

Appointed City Bacteriologist.—Miss Margaret F. Upton, formerly connected with the laboratory of the New York Post-Graduate Hospital, has been appointed city bacteriologist of Utica.

Encephalitis Lethargica.—According to the records of the New York City Health Department there have been reported from January 1 to March 9, 175 cases of encephalitis lethargica with forty deaths. It is said that there are more cases at present than at any previous time.

Drug Clinic Closed.—The drug clinic of the municipal health department which was opened last April after a series of federal raids which lessened the illicit traffic in narcotics and caused suffering among drug addicts, was closed, March 6, since the need for the clinic has apparently passed.

Personal.—Dr. Wilfred T. Grenfell of the Grenfell Annual Surgical and Health Mission to Labrador arrived in New York on the *Carmania* after a three months' lecture trip abroad.—Dr. John M. Wheeler has been elected ophthalmic surgeon to the New York Eye and Ear Infirmary, succeeding Dr. John E. Weeks, who has been appointed consulting surgeon to the institution.

New York University Medical Alumni to Organize.—A meeting has been called by the organization committee, of which Dr. Robert J. Carlisle is chairman, for March 24, at the Carnegie Laboratory for the purpose of organizing the medical alumni of New York University. There are more than 6,000 living alumni of the medical school and it is believed it will prove one of the strongest alumni organizations among medical schools in this country.

PENNSYLVANIA

Chemists Die.—Leonard Merritt Liddle, aged 26, research chemist of Mellon Institute, Pittsburgh, died, February 21.—Dr. Francis C. Phillips, aged 69, retired dean of the chemistry department of the University of Pittsburgh, and a member of the faculty for more than forty years, died, February 16.

Pennsylvania Bacteriologists Organize.—March 9, the bacteriologists of Eastern Pennsylvania met in the laboratory of hygiene of the University of Pennsylvania, Philadelphia, and organized a local branch of the Society of American Bacteriologists, electing Dr. David H. Bergey, Philadelphia, chairman; Dr. Courtland Y. White, Philadelphia, secretary-treasurer, and Dr. Claude P. Brown, Ambler, a member of the executive committee. The society will meet on the second Tuesday of each month, excepting June, July and August.

Philadelphia

Four Physicians Held.—Charged with violation of the state advertising act, four physicians were held under \$500 bail for court yesterday by Magistrate Macleary. They are: Drs. David Weissman, Lawrence Kauffman, Marshall A. Davis and Harry Y. Messec. The arrests followed written complaints to Mayor Moore.

Obstetric Societies' Joint Meeting.—March 9, the Philadelphia Obstetrical Society was the guest of the New York Medical Society. Clinics were held throughout the day in New York. In the evening a dinner was held at the Hotel Pennsylvania. Dr. Edward P. Davis read a paper entitled "Intestinal Infection in Pregnancy, Labor and Puerperium."

Memorial to Dr. Wood.—A special meeting of the College of Physicians was held, March 19, as a memorial to Dr. Horatio C. Wood. Dr. George E. de Schweinitz read a memoir of Dr. Wood. "Recollections of a Pioneer in Pharmacology in the United States," was read by Dr. Hobart A. Hare; "An Appreciation," by Dr. Francis X. Dercum, and "Reminiscences, Chiefly Neurological and Medico-Legal," by Dr. Charles K. Mills.

Personal.—Charles R. Stockard, Ph.D., professor of anatomy at Cornell University Medical School, New York City, read a paper on "Growth Rate and Its Influence on Structural Perfection and Mental Reactions" before the Philadelphia Psychiatric Society, March 12.—Dr. Judson Daland presented his resignation as a censor of the Philadelphia County Medical Society at its meeting, February 25, after twenty years of service in that office.

More Arrests in Sanitation Drive.—March 8, thirteen persons were arrested for violation of sanitation laws, bringing the total of arrests in the last three weeks, under the direction of the health department, to more than 150. Most of the cases recently were scavengers caught in the downtown section upsetting receptacles and strewing the streets with waste. They were fined and released with a reprimand if it was their first offense. Dr. Charles L. Furbush, director of public health and charities, is determined that all violators of sanitation rules shall be vigorously prosecuted and all householders who dump ashes in the streets or who do not provide proper receptacles shall be subject to arrest.

CANADA

Health Budget.—The estimates of the Toronto board of health for 1920 amount to \$1,067,216, but the board of control cut more than \$100,000 from the estimates. For epidemics \$100,000 is allowed, and of this amount \$74,000 has already been spent.

Hospital News.—Montreal is to have a Chinese hospital. The accommodation is to be for twenty-five beds. The temporary institution has already ten patients. It is claimed to be the first Oriental hospital in Canada.—Chatham, Ont., will raise \$50,000 this year for the endowment of its general hospital.

Public Health News.—Medical inspection of schools has been inaugurated in Brantford, Ont., with Dr. Alexander in

charge.—Dr. C. Achille Daigle, Montreal, has been elected a member of the central board of the Roman Catholic School Commission of that city. •

University News.—Owing to the fact that he has been appointed British ambassador to the United States, Sir Auckland C. Geddes has resigned the presidency of McGill University, Montreal. A new principal is being sought and preference will be given to a graduate of McGill, and a Canadian.

Influenza.—Up to Monday, March 1, it was announced that in Montreal during the influenza epidemic there were 657 deaths from influenza, pneumonia, and bronchopneumonia. About fifty cases a day were being reported, March 1.—Quebec City, March 4, it was announced, had had 500 cases of influenza with only two deaths.—The total number of deaths for influenza and pneumonia in Toronto for February was 656, out of a total death rate for the month of 1,191.

Sale of Liquor.—The Manitoba liquor act has been amended. Sale of liquor by wholesale druggists has been abolished. Medical men are limited to 2 quarts a day for professional purposes and 100 prescriptions a month; hospitals, 5 gallons a day.—Hon. J. R. Boyle, attorney-general of Alberta, recently announced in the legislature of that province that the profits on the government sale of liquor had been more than \$2,000,000 in 1919; and that the illegal sale of liquor had amounted to about \$3,500,000.

Public Health Notes.—The province of Quebec has lifted the ban on Ontario residents and others journeying into Quebec. Vaccination is now no longer required.—The Superior Board of Health of the province of Quebec will shortly inaugurate a campaign against tuberculosis in that province. A committee has been appointed consisting of Drs. E. M. Desaulniers, St. Lambert, Chambly; Charles R. Paquin, Quebec; Joseph E. Laberge, Montreal, and J. A. E. Beaudoin, Montreal, as secretary, to study the question and to advise what steps should be taken to make the campaign effective.

University News.—The fund for the University of Montreal (Laval), recently destroyed by fire, has attained to more than \$3,500,000.—Toronto University needs \$4,000,000 for its reorganized medical department. Dr. George E. Vincent of the Rockefeller Foundation has been in Toronto the past week and has been conferring with the special committee of the medical department presided over by Dr. Alexander Primrose, C.B. It is planned to pay whole-time professors in medicine, surgery, obstetrics, pathology, and perhaps one or two others, \$10,000 a year. Representatives from Queens, Western at London, and from Winnipeg interviewed Dr. Vincent as to their likelihood of participating in the \$5,000,000 to be allotted to Canada for medical education from the foundation.

Personal.—Dr. Edward C. Arthur, Vancouver, B. C., has been appointed traveling medical health officer of the province.—William James Chapman, Kenora, has been D. A. M. S. Military District No. 1, Winnipeg since July last.—Dr. William Harold Graham Aspland, London, has attained the rank of lieutenant-colonel and is now living in Middlesborough, Yorkshire, England.—Dr. Howard Green Barrie has returned to Shanghai after nearly five years' service in Serbia, Egypt and Alexandria.—Herbert Eldon Roaf, London, has been appointed to the chair of physiology in the University of London, England.—Dr. George Barnes Archer has returned to Ranaghat, India, and resumed his prewar activities as medical missionary.—Gerald Allison, Picton, Ont., M. B. Tor., 1915, after serving with the R. A. M. C., has returned to Toronto and received an appointment on the staff of the Toronto General Hospital.

GENERAL

Radiologists to Meet.—The Radiological Society of North America will hold its annual meeting in New Orleans, April 23 and 24.

Throat, Nose and Ear Men to Meet.—The annual meeting of the American Laryngological, Rhinological and Otolological Society will be held in Boston, June 2, 3 and 4, under the presidency of Dr. Harris P. Mosher, Boston.

Legislation on Child Welfare.—The legislative appropriation bill which has just passed the House of Representatives contains a provision appropriating \$80,000 for the investigation and report on matters pertaining to the welfare of children and child life and especially to the question of infant mortality within the District of Columbia. This work

is to be undertaken by the Children's Bureau of the Department of Labor.

Chairman Chosen.—The following chairmen have been selected for the various sections of the annual meeting of the National Tuberculosis Association to be held in St. Louis, April 22 to 24: medical section, Dr. George Dock, St. Louis; pathologic section, Dr. Eugene L. Opie, St. Louis; advisory council, Dr. Allen W. Freeman, Columbus, Ohio, and sociologic section, Dr. Hibbert W. Hill, St. Paul.

Opportunities for Physicians in China.—The Interchurch World Movement of North America has issued a special appeal for services of medical women in the Orient. There is great need for American medical women in orthopedic surgery, and there is also great opportunity for laboratory trained women. The medical schools of Canton, Hankow, Nanking, Peking and Soochow also offer some practical opportunities.

American Life Convention.—The tenth annual meeting of the medical section of the American Life Convention was held at French Lick Springs, Ind., March 10 to 12, under the chairmanship of Dr. C. Naumann McCloud, Minneapolis. The following officers were elected: Dr. Frank L. Truitt, Indianapolis, chairman; Dr. Calvin H. English, Fort Wayne, vice chairman; Dr. Frank L. B. Jenney, Chicago, secretary (reelected), and Dr. Henry Wireman Cork, Minneapolis, a member of the board of managers.

Christmas Seals.—At a conference of representatives of state associations and the National Tuberculosis Association in Chicago, January 8 to 10, it was reported that the proceeds of the 1919 sale of Christmas seals would amount to more than \$4,100,000.—The chairman of the central committee of the American Red Cross has notified the National Tuberculosis Association under date of January 27, that the American Red Cross will discontinue the sale of seals as a means of raising funds for the organization.

Mortality Statistics.—The Bureau of the Census has just issued Bulletin No. 41, giving the mortality statistics for 1918. The bulletin includes the most important facts relative to deaths recorded in the death registration area. The states of Illinois, Louisiana and Oregon have been added to the area, so that the bulletin concerns a population of 81,868,104, or 77.8 per cent. of the total population of the United States. The total number of deaths for this area, including 26,269 soldiers, sailors and marines, was 1,471,367, corresponding to a death rate of 18 per thousand population, or 3.8 higher than the rate for 1917, which was 14.2. The great increase in the death rate was believed to be entirely due to the high mortality caused by the pandemic of influenza.

National Board of Medical Examiners Incorporated.—Senate Bill No. 3959 has been introduced by Senator Kellogg to incorporate the National Board of Medical Examiners of the United States of America. It provides that Rear Admiral William C. Braisted, U. S. Navy; Major-Gen. Merritte W. Ireland, U. S. Army; Surg.-Gen. Rupert Blue, U. S. P. H. S.; Admiral Edward R. Stitt, U. S. Navy; Col. Louis A. LaGarde, M. C., U. S. Army, retired; Asst. Surg.-Gen. William Colby Rucker, U. S. P. H. S., and Drs. Herbert Harlan, Baltimore; Isadore Dyer, New Orleans; Victor C. Vaughan, Ann Arbor, Mich.; Walter L. Bierring, Des Moines, Iowa, and such other persons as may be chosen who are members of the National Board of Medical Examiners, an unincorporated, nonprofit association known as the National Board of Medical Examiners, and their successors, are hereby created and declared to be a body corporate.

Bequests and Donations.—The following bequests and donations have recently been announced:

Blackford County Hospital, Hartford City, Ind., a donation of three city blocks in Hartford City and \$5,000 for improvements thereon by Mrs. H. B. Smith in memory of her husband.

For a free hospital for Indians near Henrietta, Okla., \$1,000,000 by Jackson Barnett, an Indian of Oklahoma made wealthy by oil.

McGill University, Montreal, \$5,500 for a scholarship in medicine in memory of his son, Lieut. Walter W. Hoare, by Dr. Charles W. Hoare, Walkerville, Ont.

Harbin Hospital, Rome, Ga., a donation of radium costing between \$6,000 and \$10,000 by J. P. Cooper.

Mercy Hospital, Chicago, \$250,000 by the will of Charles E. Haines, St. Charles.

Women's Medical College of Pennsylvania, Philadelphia, \$4,000 for an endowment to educate a woman medical missionary for work in China, by the Board of Foreign Missions of General Synod of the Reformed Church.

Michael Reese Hospital, Chicago, \$200,000 by the will of Otto Baer. American Hospital, Paris, a donation of 4,946,000 francs by Mrs. Robert Bacon, widow of the late American ambassador to France for

the endowment, in memory of Colonel Bacon, of twenty-four beds in free wards of the hospital to be built at Neuilly. Mr. Henry P. Davison of the American Red Cross has transferred 750,000 francs, the remainder of one of the war funds of which he was chairman, to the American Red Cross Hospital in France to that part of the hospital devoted to the Bacon free wards.

Lankenau Hospital, Philadelphia, \$5,000 by the will of Gustaf A. Schwartz.

Legislation on Mailing of Chemicals.—Congressman Halvor Steenerson of Minnesota has favorably reported from the Committee on Post Offices and Post Roads a bill amending the penal code of the United States which forbids the transmission through the mails of "all kinds of poison" and "chemicals." The bill as reported will permit the postmaster-general to make regulations on this general subject. In a letter to Congressman Steenerson, Postmaster-General Burleson says:

"There is a widespread public demand for the admission to the mails of certain classes of matter, and the proposed legislation is designed to meet this demand. Many requests from manufacturers, chemists, physicians, surgeons, druggists, dealers in medicines and their associations, etc., to extend to them the facilities of the parcel post for the transportation of medicines and drugs, have been received, it being urged that the exclusion of such matter from the mails works a peculiar hardship on physicians, druggists, dentists and veterinarians who are located at points remote from express offices, they having no direct way under the present law of getting small shipments of drugs. The manufacturers and dealers are equally interested, as the parcel post is the only direct way of communicating with persons authorized to handle habit-forming drugs."

The law as amended will permit the sending through the mails of poisons, chemicals, and other articles hitherto forbidden, under special regulations relating to the subject made by the Post Office Department. The bill specifically provides, however, that these articles are to be sent "from the manufacturer thereof or dealer therein, to licensed physicians, surgeons, dentists, pharmacists, druggists and veterinarians."

FOREIGN

Vaccination Compulsory in Czechoslovakia.—It is said that a law of date of last July makes vaccination compulsory in Czechoslovakia during the first year and again at the completion of the seventh and of the fourteenth years.

Credé Centennial.—Both the method of placental expression and the silver-nitrate prophylaxis of ophthalmia neonatorum were introduced by K. S. F. Credé of Berlin, the centennial of whose birth was recently celebrated in Germany.

British Medical Association Meeting.—The next annual meeting of the British Medical Association will be held in the University of Cambridge in the last week in June under the presidency of Sir Thomas Clifford Allbutt, who was president of the association at the opening of the war, since which time no meeting has been held.

Requirements to Practice in Hayti.—A communication from a reliable source states that physicians of the United States who desire to enter practice in Hayti may become qualified to do so by presenting their original diploma of graduation from medical schools and evidence of their preparation and licensure to the National School of Medicine, Port au Prince, Hayti.

Predetermination of Sex.—The German medical society organized at Berlin for research on sexual science and eugenics has offered a prize of 1,000 marks for the best article on the subject, "Has Man Two Kinds of Spermatozoa?" The question is to be studied by the light of modern views on predetermination of sex. The secretary of the society is Dr. M. Hirsch, Motzstr. 34, Berlin.

Poisoning from Beans.—The German medical journals state that Professor Lewin of Berlin warns that beans should not be allowed to be imported that contain more than 20 mg. hydrocyanic acid in 100 gm. of the beans. There have been several cases of vomiting and diarrhea keeping up for ten or twelve hours after ingestion of imported beans of the *Phaseolus lunatus* family. This includes butter, sugar and lima beans and the bitter or Egyptian bean.

Personal.—A gold medal and 5,000 francs, representing the Lannelongue prize, was awarded recently by the French Society of Surgery to Dr. H. Gaudier of Lille, for his pioneer work in the excision and immediate suture of war wounds. —Dr. Léon Bernard, professor of medicine, Faculty of Medicine, Paris, has been elected a member of the Academy of Medicine, and Drs. Lesbre, Lyons, and Lignières, Buenos Aires, have been elected corresponding members. —Prof. Thomas Swale Vincent has been appointed to the university chair of medicine tenable at the Middlesex Hospital Medical College, London.

Deaths in the Profession Abroad.—Dr. W. Busse, professor of gynecology at the University of Jena, aged 46.—Dr. H. Weicker, physician in chief of the Göbersdorf sanatorium.—Dr. P. Mayet of Berlin, a statistician and writer on social hygiene. He is credited with the initiative for the government pension now granted to parturients.—Dr. L. Pinatelle, formerly professor of surgery at the University of Lyon, aged 46.—Dr. Cecil Rupert Chaworth Lyster, director of the radiotherapeutic department of Middlesex Hospital, London, died, January 26, from the effects of roentgen-ray burns for which repeated operations had been performed.

Tribute to the Heroes in the Profession During the War.—A subscription has been opened under the auspices of all the medical schools and organizations of France to collect funds to honor the memory of the medical victims of the war. It is planned to issue a souvenir volume, the *Livre d'or*, to contain the names and citations of all the physicians and medical students who died for France, in whatever service they may have been engaged. Dr. Caboché, 372 rue Saint-Honoré, Paris, is in charge of this part of the work, collecting private data to control the state archives. A copy of the volume will be presented to every one who subscribes at least 40 francs. A monument is also planned and subscriptions are being received for this purpose throughout France. The treasurer general is Dr. Bongrand, 6 rue Villaret-de-Joyeuse, Paris.

Foreign Guests Visit the United States.—At the invitation of members of the National Board of Medical Examiners, who visited England and France during 1919, several prominent physicians from abroad will visit America and make a tour of the country and attend the annual meeting of the American Medical Association in New Orleans. These guests are:

Sir Humphrey Rolleston, F.R.C.P., London; appointed by the president of the Royal College of Physicians, London.

Col. H. J. Waring, F. R. C. S., London; appointed by the president Royal College of Surgeons, England. Representing Conjoint Board of England.

Dr. Norman Walker, Edinburgh, representing the Triple Qualification Board of Scotland.

Professor Gregoire, surgeon, and Professor Roussy, physician; appointed by the dean of the faculty of medicine, University of Paris.

This commission will be joined by Prof. J. C. Connell, Kingston, Ontario, president of the Medical Council of the Dominion of Canada.

Merger of French Journals of Gynecology.—It is announced that a new journal, to be entitled *Gynécologie et Obstétrique*, is to be issued as a merger of the three leading French journals in this field. It takes the place of the *Archives mensuelles d'Obstétrique et de Gynécologie* which Bar and Faure have been guiding so long and which in turn was the successor of the *Obstétrique*; also of the *Revue de Gynécologie*, Pozzi's handsome journal which stopped with the war and his death, and of the *Annales de Gynécologie et d'Obstétrique*, the directors of which included Pinard, Hartmann and Pollosson, with Convelaire and Lecène in charge. The new journal is to appear monthly, to be issued by Masson et Cie, 120 boulevard Saint-Germain, Paris. The subscription is 50 francs. All the three journals which it succeeds have been regularly indexed in the Current Literature department as they were issued, practically since the department was founded.

LATIN AMERICA

Influenza Epidemic in Panama.—Influenza has assumed an epidemic form in Panama, and the hospitals of Colon are filled with patients.

Epidemic of Meningitis in Havana.—The epidemic of cerebrospinal meningitis in Havana continues to spread. During the last few days a number of deaths have occurred among the personnel of the Cuban navy.

Personal.—Prof. B. A. Houssay of the University of Buenos Aires has been elected corresponding member of the Société de Pathologie exotique at Paris in token of appreciation for his extensive research on snake venom and on scorpion and spider poisons.

Deaths in the Profession.—Dr. J. J. Mon of Buenos Aires, hospital physician and writer, aged 40.—Dr. F. Castro Rabello Kock, professor of therapeutics at the University of Bahia and official of the state public health service, aged 39.

—Dr. J. de Verney Campello, professor of microbiology at the University of Rio de Janeiro, aged 37.—Dr. A. de Arruda Beltrão, a prominent physician at Rio de Janeiro and official health officer, aged 54.—Dr. E. J. Corbellini, formerly professor suplente of surgery in the University of Buenos Aires, *consejero* of the university and a leading surgeon of the capitol, aged 47.

Government Services

Changes in Public Health Service

The President has sent to the Senate the nominations of former Surgeon-General Rupert Blue and Joseph H. White to be assistant surgeon-generals at large of the public health service.

Disease Conditions in the Army

For the week ending March 5, a few cases of influenza were reported from nearly all of the large camps and stations. At Camp Taylor the epidemic appeared to be subsiding much more slowly than at other camps, the personnel at this camp being nearly twice as large as at any other. The whole epidemic is considered at an end, so far as it affects the military service.

Influenza in the Navy Personnel

The influenza epidemic of 1920 affected the Navy as it did the civilian population. The recurrence began during the week ending January 17 at Great Lakes, Ill. On January 12 there were fifty-one cases. The peak was reached on the third day with the admission of 182 new cases during twenty-four hours. Although the peak came earlier than in the 1918 epidemic, the decline was less rapid and there were four secondary peaks, the outbreak terminating on the twenty-fourth day. It is reported that on the whole the epidemic was less severe and the cases milder during 1920 than during 1918. Pneumonia was a complication in about 10 per cent. of the reported cases of influenza. In addition to the epidemic at Great Lakes, which included in all 1,415 cases, there were 3,354 cases in other stations.

European Health Conditions

Surgeon-General Hugh S. Cumming, U. S. P. H. S., returned from his duties in Europe, where he has been stationed for two years, to assume his new position in Washington, March 10. Dr. Cumming says that typhus is far from being checked and seems to be increasing, so that there is imminent danger of an epidemic raging over Europe on a large scale, unless the most strict quarantine and other control measures are enforced. With the disease entrenched in European ports, the next danger point will be the United States, and he believes that nothing should be left undone to keep out this disease as well as bubonic plague. An agency is soon to be established under the League of Nations which will coordinate and strengthen the health work of all nations and will particularly improve the reporting of diseases and maintenance of international quarantine. April 12, a meeting is to be held in London, to which representatives of the health departments of various nations have been invited, when it is believed a permanent organization will be formed.

Contract Surgeons Under Army Reorganization Bill

Pressure is being brought to bear on members of the House of Representatives for recognition in the Army reorganization bill of former contract surgeons of the Army. The Army bill as it was reported to the House fails to credit contract surgeons and assistant surgeons for their service in the Army, which service in part determines their claim for longevity pay and retirement. The Army reorganization bill now pending in the Senate gives full credit to contract surgeons for their service in the Army, but the Army reorganization bill pending in the House is silent with reference to such recognition for contract surgeons. It is the general feeling that contract surgeons have not received justice in the House bill nor been accorded the recognition which is due them. When the American soldiers went to the Philippines and later to China the greater part of the work of the medical department was performed by acting assistant surgeons. It was seldom if ever that a regular medical Army officer was at that time on active duty with troops.

The War Department asked for volunteer acting assistant surgeons to meet the demand for medical officers. Physicians who thus entered the service signed a contract with the surgeon-general to perform the duties of a first lieutenant. Technically, however, such physicians were not army offi-

cers but were termed contract surgeons, although they performed the duties and were exposed to the hardships of the regular medical officer in the Army. As it does not seem likely that the House bill can be amended at this late time, it is felt that the Senate committee on military affairs will insist on recognizing the claims made in behalf of the contract surgeons.

Foreign Correspondence

LONDON

Feb. 21, 1920.

The Prevention of Venereal Disease

The prevention of venereal disease is still a burning topic. A largely attended public meeting, convened by the Society for the Prevention of Venereal Disease, has been held at the Mansion House under the presidency of the lord mayor. A resolution was carried unanimously that venereal disease had become a menace to national health and prosperity, and in view of the fact that infection can be prevented by self-disinfection immediately after exposure, it is necessary to instruct the public as to the importance and method of doing this. These instructions for immediate self-disinfection have been issued by the society: Materials required: cotton wool; a solution of potassium permanganate, in 1:1,000; calomel ointment, 33 per cent. (A) If exposure takes place outdoors or where complete disinfection is impracticable: (1) Make water. (2) Soak a swab of cotton wool with the solution. Draw back the foreskin, carefully swab the head of the penis and undersurface of the foreskin, especially at the opening of the pipe. These steps must be taken within an hour of exposure. (3) On returning home, thoroughly wash the sexual organs with soap and water and well rub the ointment into the penis, drawing back the foreskin. This must be done within six hours of exposure. (B) If exposure has taken place within doors, a more complete immediate disinfection should be made: (1) Make water. (2) Wash the sexual organs and parts around with soap and water. (3) Swab with the solution. (4) Rub the ointment well into the penis. The swabbing with the permanganate is the most important measure. An additional safeguard is to apply the ointment before intercourse. If exposure has occurred under the influence of alcohol, so that the precautions recommended have not been promptly taken, the chances of infection may be considerably lessened by carrying out "B," well rubbing in the ointment for ten minutes and in addition syringing the pipe with permanganate solution of half the strength recommended for the outside, and holding the solution in for two minutes by pinching the lips of the pipe. This method is useless after twelve hours. If none of these precautions have been taken, and there is reason to believe that infection is probable, a physician should be consulted at once.

The subject has also been considered by the Medical Women's Federation, which has issued a pamphlet stating that the chief and most important part of the task with which society is faced is such a reform of our social structure and moral habits as will gradually eliminate conditions which have led to the prevalence of venereal disease. In regard to prophylaxis, the federation associates itself with the findings of the interdepartmental committees on infectious diseases in connection with demobilization. The committee found that even under the conditions of discipline of men on active service, the "prophylactic packet system" was a failure. The provision of clinics open at all hours of the day and night for early preventive treatment so that sterilization may be carried out within a short time of the act is also condemned as encouraging and countenancing promiscuous intercourse. "The sale by chemists of calomel ointment or permanganate solution is a matter with which we have no concern as long as the public is aware that these things are not remedies for venereal disease."

Graduate Teaching Units

The reorganization of the teaching of several of the London hospitals by the formation of medical and surgical units under directors who, with their assistants, are entirely engaged in this work, has been described in previous letters to THE JOURNAL. An incentive to this reform is the fact that educational grants toward the expense can be obtained from the government. The London School of Tropical Medicine, the teaching of which is entirely graduate, is also adopting

the scheme. Whole-time directorships have been instituted in protozoology, helminthology, entomology and tropical pathology.

War Section of the Royal Society of Medicine

An innovation at the Royal Society of Medicine has been the formation of a war section. At the first meeting a discussion on gas poisoning in warfare was opened by Sir Wilmot Herringham, who described his introduction to this method when in April, 1915, he came across three French (Algerian) soldiers in a Canadian ambulance suffering from the effects of chlorine gas sent over by the Germans in the form of clouds or drifts. Three days later he found 600 or 700 men in hospital at one center, all suffering from its effects. They were gasping for breath, coughing, and expectorating yellow, frothy fluid, which often ran out of their mouths when they lay on their sides. No treatment seemed to avail. The method of using oxygen customary in pneumonia was not of the slightest use. Experiments were immediately made in England to elucidate the pathology, and it was shown that the chief symptoms might be explained by the difficulty of oxygen entering the blood through the great wall of edema. The mainstay of treatment was oxygen, which was administered at first by a makeshift apparatus of gasoline tins until Dr. Haldane's apparatus became available. It appeared that as far back as 1909 the Germans were preparing to use gas in war. In that year a research chemist from this country, who periodically visited Germany, was walking in the country when he detected a strange odor. He came to a small hill on which were soldiers and some sheep, of which several appeared to be dead. He was not allowed to go farther. Evidently he had come on some poison gas practice for military purposes.

Prophylactic Inoculation Against Influenza

Sir William Leishman, director of pathology at the War Office, has published the first records of the results of prophylactic inoculation against influenza according to the method described in a previous letter:

	Number of Men	Ratio per Thousand		
		Incidence of Attack	Lung Complications	Deaths
Inoculated	15,624	14.1	1.6	0.12
Noninoculated	43,520	47.3	13.3	2.25

Not only do these figures show a great advantage for the inoculated, but there is the additional fact that nearly one half of them received only a third part of the dose considered necessary.

A Majority of Women on the General Health Council

The Consultative Council on General Health Questions, established under the Ministry of Health, has held its first meeting. Dr. Addison, who presided, asked the council to put before him a statement of the main defects in existing provisions for safeguarding the health of the people, and to suggest remedies from the standpoint of the general public. Women form a large majority of the council and represent a number of trade organizations, such as the United Textile Factory Workers, the Women's Cooperative Guild, the National Council of Women of Great Britain and Ireland, and the Labor Party.

War Patients Still in the Hospital

Impressed by the fact that many medical and surgical cases have remained in military hospitals beyond the period when benefit is being derived, the medical authorities of London district have appointed a board of consultants to investigate the matter. They will visit the hospitals and advise the best method to be adopted for the patient's recovery and disposal. The board will consist of Col. H. J. Waring, president (surgeon); Major W. E. Wynter (physician); Capt. C. M. Hinds Howell (neurologist), and Col. T. H. Openshaw (orthopedic surgeon).

Election of Honorary Fellows of the Royal College of Surgeons

A. Depage, Brussels; Pierre Duval and A. Gosset, Paris; J. M. T. Finney, Johns Hopkins University, and Charles H. Mayo, Rochester, Minn., have been elected honorary fellows of the Royal College of Surgeons. It is hoped that they may be able to attend the meeting of the council in July for the presentation of diplomas.

VIENNA

Feb. 24, 1920.

Death of Professor Wertheim

A few days ago, Professor Ernst Wertheim, the famous gynecologic surgeon, died rather suddenly from the effects of an attack of the so-called influenza, which at present is prevalent in Vienna. He was only 58 years of age. Wertheim's reputation was worldwide, and there will be a large number of men in the United States who will regret to hear of his death. His chief line of work was the surgical treatment of cancer of the uterus, and his method of operation was at one time regarded as the best operation for this disease. Wertheim was a critical and exact scientist. As an operator he was bold and original, and as a teacher he was unique. With his death, which followed so soon after the death of Professor Schauta, there has occurred a rare condition in the University of Vienna. Both clinics for diseases of women are now free as both directors are dead. It will be difficult to find two suitable men to fill the vacancies. In Austria there is just now no abundance of such men, as no physician from Germany will at present be willing to come to Vienna, which does not offer much financial attraction. On the other hand, only a first-class man, who is able to teach and to do research work, can be appointed to this important post.

Influenza and Lethargic Meningitis in Vienna

At present a wave of influenza (grip) is raging in Vienna, which is not quite as bad as last year, and is distinctly different in its clinical manifestations. A new feature of the disease besides the well-known complications of the lungs and the brain is a spasmodic condition of the intestines, as reported by Dr. Massery in a paper read recently before the Medical Society of Vienna. He has seen six patients in the Samaritan Hospital who, when first seen, showed a condition resembling most closely acute strangulation of the intestine, severe pains all over the abdomen, spasms, and continual and absolute constipation. Pulse and temperature, however, remained not far from normal. Operation proved that the occlusion was due not to an obstacle, but to severe spasms of the intestinal muscles. Two cases could not be saved; death was probably due to the spasmophilic condition so often observed in cases of grip.

Another group of cases showed complications of another type of spasms; these resembled chorea. Spasms occurred in different groups of muscles, the flexors or extensors of the limbs, or of the abdominal walls. The patients were delirious, the temperature rose to 40 C. and higher and severe somnolence was always present. Seventy-one cases, of which thirty-one were fatal, were reported by Dr. Dimitz, from the neurologic clinic, at the above-mentioned meeting. The postmortem findings showed only a more or less marked hyperemia and sometimes edema of the brain, chiefly in the lenticular region. Similar epidemics appeared in various towns of Austria, lasting six weeks altogether. Lethargic meningitis is now also often observed. The patients are mostly young or middle aged persons (12 to 50 years); the mortality is rather high—20 per cent.—as etiologic treatment has not yet been possible. Pneumococcus serum seems to have a beneficial influence.

Medical Men Strike

The political weapon, the strike, which so often has been adopted with more or less success in economic warfare between capital and labor, has now been taken up, for the first time in this country, by medical men anxious to secure a modest living. The first strike was arranged by physicians of the "Krankenkasse" or sickness insurance society, who demanded an increase of their moderate fee at the rate of trebling their antewar fee. It must be added that at present the cost of living is forty times as great as before the war. As these physicians devote only part of their time to this "panel" work, their demands have been low. Hitherto the "Krankenkasse" has refused the new rate of remuneration, and so the medical men no longer treat the members on the old terms but as private patients. Public feeling is in favor of the physicians, so the result is not doubtful. A similar "difference of opinion" has sprung up in our clinics. Hitherto only the assistants and two house physicians were paid in the clinics. All other physicians, the outpatients' assistants as well as other physicians working in the clinics and, so to speak, making the thing "run," were working gratuitously. Now the enormous cost of living is so heavy that these men, too, demand from the board of education, to whom the

clinics belong, a moderate remuneration and free board. As the work of these doctors is indispensable for the good working order of the clinics and since the government has refused to comply with the wishes of the men, they applied to the "Medical Organization," comprising 99 per cent. of all medical men of Vienna, for help. The organization proclaimed, after futile negotiations, a clinical strike, which lasted only a few hours. They attained their object. The leading rule in the new understanding is: "No work without payment, but only those men will be admitted whose work is required for the clinics, and the number will be restricted to the actual needs."

PARIS

Feb. 12, 1920.

Symbiosis, a Biologic Theory

A book that appeared recently entitled "Les symbiotes" has awakened a lively discussion. The personality of the author has been known for many years in the scientific world. The name of the author in question is Paul Portier, "maitre de conférences" on the Faculté des sciences de Paris and professor at the Institut océanographique, who took a prominent part in the investigations of Prof. Charles Richet on anaphylaxis. The above mentioned work would overthrow completely the ideas heretofore entertained concerning the rôle of microbes. To be sure, it was already known that all microbes are not pathogenic and that certain phenomena of life depend on the existence of bacteria. But the theory of Portier has a much more general application, for he states that every living cell is composed in reality of two cells that are associated in symbiosis; the human organism must be regarded, then, as the host of innumerable microbes dwelling in the protoplasm of the cells. The presence of the symbionts is constant and necessary, Portier thinks; without them life would be impossible. All the phenomena of intercellular organic changes, and more especially the phenomena of intercellular synthesis depend, accordingly, on the symbionts. The phenomena of "deficiency," which in recent times have attracted attention to the consideration of the interesting subject of vitamins, would likewise be explained, it is maintained, by the rôle of the symbionts. They play a part, it would seem, in the process of fecundation, in experimental and physiologic parthenogenesis, and also in the phenomena of immunity. Portier has succeeded in isolating and cultivating the symbionts, which are nothing more than the elementary structures of the cells and the blood described by the biologists under such names as "mitochondria" and "globulins." However, it is only proper that I should add that this biologic theory has been attacked by Auguste Lumière of Lyons, who has written a book entitled "Le mythe des symbiotes" (The Myth of the Symbionts).

Physicians as Affected by the Tax on War Profits

A law dated July 1, 1916, put a special tax on war profits. It has been an undecided question whether physicians were subject to this tax. The matter has now been threshed out before the Conseil d'Etat, where a physician upheld the view that this special tax affected only those engaged in industrial and commercial pursuits. The counsel of the physician pleaded that it was not the intention of the law to include the professions, and much less the medical profession, which is bound by the right of privileged communication. But the minister of finance stated in reply that the text of the law would indicate that it applied in general to persons, subject to licensure, whose benefits and profits during the war exceeded those of normal times. The Conseil d'Etat, therefore, reached the decision that, in view of the general terms of the law, it was right and proper to tax all subject to licensure whose emoluments exceeded those that their profession normally produced, without making any distinction as to the nature of the profession and without considering the attitude usually taken toward the resources from which they derive their income. The decree adds that, even though it could be shown that the emoluments realized by certain persons thus included, by reason of the conditions under which they exercised their profession, would, of necessity, require a special limitation in the application of the law, such fact would not be of such a nature as to exonerate them completely. Consequently, the medical profession, which, according to the law of 1880, is subject to licensure, has been declared subject to the tax on war profits.

The Reorganization of Night Medical Service

So far the organization of night medical service in Paris has been anything but satisfactory. The present service

dates back to 1876, and since that time it has undergone no changes by way of reform. The main features of the service as it has existed in the past were that, in each quarter of the city, physicians were asked to state whether they desired to respond to night calls or not. The names and the addresses of those who had signified a willingness to give night service in any given quarter of the city were inscribed in a directory which was kept at the police station of that quarter. The person who was in need of a physician at night went to the police station, and a policeman was delegated to accompany such person to the home of the physician and also went with the physician to the home of the patient. When the physician had finished his visit, the policeman gave him an order on the prefect of police for 10 francs. It is almost needless to say that this mode of service was primitive. The fact of having accepted night service did not put the physician concerned under any obligations to stay at home nights in anticipation of a call; so that it often happened that the physician to whom the delegated policeman and the person in need of medical assistance went was not at home. It thus became necessary to call on another physician, who might also be away as was the first. In view of the weaknesses of the old system, an endeavor has been made to reorganize the service with the following two prerequisites as a basis: 1. It was realized that in order to make a night medical service effective it would be necessary that certain physicians should be "on call" during the entire night and ready to render service to any patients who were in urgent need of attention. 2. It was equally apparent that the service should be organized in such a manner that physicians could be summoned quickly and also be in a position to reach the patient promptly.

With these ideas in view, the old system by which the names of physicians willing to do night service were inscribed in a special directory has been abolished, and a panel of physicians selected by a competitive examination and directly subject to the authority of the prefect of police has been established. These physicians so selected will serve for three years, at most, and will receive a fixed annual compensation of 3,000 francs. The city of Paris has been divided into five sections, in each of which a physician will be found (when not otherwise on duty) from 10 p. m. to 7 a. m., from October 1 to March 31, and from 10 p. m. to 6 a. m., from April 1 to September 30, at the disposal of patients who make request for medical service at night. The office of such physicians will be at a police station centrally located. A room with a bed will be provided, so that physicians will have the opportunity of resting, if they so desire, when not on active duty. A request for a physician is made at the nearest police station, which immediately communicates the request by telephone to the central police station. An automobile is sent to convey the physician to the residence of the patient and back to his post of duty. Each automobile used for this purpose is provided with a first-aid medical chest containing a small supply of drugs and surgical instruments. The night service is so organized that a physician is on duty only one night out of six. Each physician will therefore be on duty sixty nights a year, so that with 3,000 francs per year he will be receiving 50 francs for each night that he serves. This compensation is sufficient to secure the services of young physicians who have not an established practice as yet. The regulations provide that physicians serving on this panel shall be under 30 years of age, though former hospital interns may be up to 35.

Marriages

ALVAN LOTHAIK CHAPMAN, Hermanville, Miss., to Miss Mary Belle Hollingsworth of Crystal Springs, Miss., February 28.

JEROME J. ROBBINS, Gulfport, Fla., to Mrs. Elizabeth Tabor of Hubbardston, Mich., at Gulfport, recently.

ROBERT WILLIAM O'DONNELL, Mobile, La., to Miss Jennie May Conway of Shreveport, La., February 19.

G. C. McCLURE, Ball Ground, Ga., to Miss Pearl Gohier of Dawsonville, Ga., at Atlanta, February 25.

MYER NORMAN MOSKOVICH, St. Paul, to Miss Elizabeth Garfinkel of Philadelphia, January 5.

LYMAN JACKLIN SPALDING, New York City, to Miss Dorcas Parker of Bryan, Texas, recently.

Deaths

Louis Anatole LaGarde, Col., M. C., U. S. Army (retired); while returning from attendance at the meeting of the National Board of Medical Examiners in Chicago, was stricken with cerebral hemorrhage, March 7, and died just as the train was entering Pittsburgh. Colonel LaGarde was born in Bayou La Fourche, La., April 15, 1849, and after attending the Louisiana Military Academy, was graduated from Bellevue Hospital Medical College in 1872. After his internship in Roosevelt Hospital he entered the Army as contract surgeon in 1874, and served during the Sioux War. He received his appointment in the Army as first lieutenant and assistant surgeon, June 6, 1878, and then served on frontier duty for twenty years, during which time he was promoted to captain and major. In 1892 and 1893, he was detailed by the War Department to test the new rifle for the Army. During the war with Spain, he was in command of the divisional reserve hospital of the Fifth Army Corps at Siboney, Cuba, and was in charge of the evacuation of sick and wounded to northern hospitals, until he was stricken with yellow fever. Since 1899 he has been professor of military surgery in the University of the City of New York, and was also lecturer on gunshot wounds and ophthalmology in the Army Medical School from 1901 to 1902. In 1903 and 1904, Colonel LaGarde was made president of the board to determine the stopping power of bullets for pistols and revolvers with a view to a more effective service weapon. From 1904 to 1905, he was superintendent of the Ancon (Canal Zone) Hospital, and from 1905 to 1908, was the chief surgeon of the Department of the Visayas, Philippine Division, and while on this detail was made lieutenant-colonel and deputy surgeon-general. He was then made chief surgeon of the Department of Colorado, was promoted to Colonel, M. C., Jan. 1, 1910, and was retired by operation of law, on attaining the age of 64, April 15, 1913. Since that time Colonel LaGarde has been active as superintendent of the National Soldiers' Home, Washington, D. C., and as a member and treasurer of the National Board of Medical Examiners. He was recalled to active service during the World War, and in addition to his other duties delivered lectures on the medical reserve corps, and on military surgery at various medical colleges, throughout the country. He was an authority on ballistics, and his work on gunshot wounds was a standard textbook up to the time of the World War. He was a Fellow of the American Medical Association and in 1903 was a member of the House of Delegates representing the Army. He was also a charter member of the Association of Military Surgeons of the United States, and served for a time in 1918 as interim treasurer and editor of the *Military Surgeon*. Colonel LaGarde was a Southern gentleman of the old school, a charming companion and a most delightful personality.

Kenneth Alexander J. MacKenzie • Portland, Ore.; McGill University, Montreal, 1881; aged 61; L.R.C.P. and L.R.C.S. (Edin.), 1882; second vice president of the American Medical Association in 1905, a member of the House of Delegates in 1904, 1912 and 1913, and chairman of the committee of arrangements for the Portland meeting; a fellow of the American Surgical Association; president of the Portland Academy of Medicine in 1909 and 1910; once president of the Oregon State Medical Association, and Portland City and County Medical Society; captain, M. C., U. S. Army, and discharged, Jan. 31, 1919; aide to the governor of Oregon under the Selective Service Act; professor of theory and practice of medicine from 1887 to 1907, professor of operative and clinical surgery since 1917, and dean of the faculty of the University of Oregon since 1912; surgeon to St. Vincent's Hospital, Portland, since 1883; chief surgeon for Oregon and Washington of the Oregon Railroad and Navigation Company since 1895; a director of the United States National Bank; head of the relief corps of physicians and nurses at the time of the San Francisco fire and earthquake, and in charge of the Harbor View relief station; and medical director of the Lewis and Clarke Exposition; director of the Portland Free Dispensary; died, March 15, from heart disease following influenza.

Charles Knox Cole, Chelsea-on-Hudson, N. Y.; Miami Medical College, Cincinnati, 1879; aged 67; at one time president of A. Schrader's Son, Inc., Brooklyn, the largest manufacturers of submarine divers' apparatus in the world; founder and director of the Rocky Mountain Club in New

York City; for many years a prominent figure in Montana, where he was a member of the city council of Helena, president of the Montana Senate, president of the state board of examiners, and chief surgeon of the Montana Central Railway; president of the American Academy of Railway Surgeons in 1894, and secretary and treasurer of the American Association of State Examining and Licensing Boards in 1892; died in Pasadena, Calif., March 1.

William King Rogers • Columbus, O.; University of the City of New York, 1889; aged 53; a member of the American Academy of Ophthalmology and Oto-Laryngology; American Ophthalmological Society, and American Otological Society; professor of otology in the Medical Department of the Ohio State University, Columbus, since 1900; attending surgeon to Mt. Carmel, and St. Francis hospitals, and consulting surgeon to the Children's Hospital, Columbus; formerly president of the Ohio State Board for the Relief and Benefit of the Needy Blind; died in Mt. Carmel Hospital, Columbus, February 27, from septicemia.

Herbert William Yemans • Major, M. C., U. S. Army, Alcatraz, Calif.; Detroit, Mich., Medical College, 1878; aged 62; a member of the Association of Military Surgeons of the United States; an officer of the United States Marine Hospital Service from 1882 to 1887, and from 1892 to 1894; contract surgeon, U. S. Army since 1903; formerly a member of the council of the Manila Medical Society and Philippine Islands Medical Association; an expert on Esperanto; who was retired from the Army recently on account of physical disability; died at Fort Rosecrans, Calif., January 29.

George Clarke Ober, Washington, D. C.; Georgetown University, Washington, D. C., 1882; aged 59; a member, secretary, and once first vice president of the Medical Society of the District of Columbia; from 1891 to 1903 professor of materia medica and therapeutics and later of practice of medicine in the National University; for nine years secretary and later president of the District Board of Medical Examiners; formerly president and for four years secretary of the Board of Medical Supervisors for the District; died in Providence Hospital, February 25, from erysipelas.

Thomas Amory DeBlois, Boston; Dartmouth Medical School, Hanover, N. H., 1878; University of the City of New York, 1878; aged 72; a member of the Massachusetts Medical Society; a member and once vice president of the American Laryngological Association; a graduate of the United States Naval Academy in 1868; laryngologist and surgeon to the Boston City Hospital; instructor in laryngology at Harvard University Medical School; Lieutenant-Commander and Surgeon of the Naval Brigade, Massachusetts Volunteer Militia; died about February 29.

Joseph Eddy Clark, Utica, N. Y.; Harvard University Medical School; a member of the Medical Society of the State of New York and the Massachusetts Medical Society, 1882; a specialist in diseases of the nervous system; for twelve years in charge of the Vanderbilt Clinic, New York City; for several years chairman of the Board of Health of Medford, Mass.; since 1914, sanitary supervisor of the New York State Department of Health for Oneida, Herkimer and Madison counties; died in the Utica General Hospital, March 4.

Peter Lawrence Schenck, Brooklyn; College of Physicians and Surgeons in the City of New York, 1865; aged 76; a member of the Medical Society of the State of New York; a life member of the American Academy of Medicine; acting assistant surgeon U. S. Army during the Civil War; medical superintendent to Kings County Hospital from 1872 to 1881, and consulting surgeon to the institution from 1882 to 1914; visiting physician to the Kings County Penitentiary from 1889 to 1905; died March 6.

William Edwards, Bowdle, S. D.; College of Physicians and Surgeons, Keokuk, Ia., 1873; Northwestern University Medical School, Chicago, 1875; aged 70; a member of the South Dakota State Medical Association and a life member of the Mayo Surgeons' Club; president of the Board of Councilors of the State Medical Society; first mayor of Bowdle; state senator in 1892 and later a member of the state board of health; died, February 8, from carcinoma of the stomach.

Gustav Adolph Thiede, Baltimore; Maryland Medical College, Baltimore, 1901; aged 47; a member of the Medical and Chirurgical Faculty of Maryland; formerly health warden, and school inspector of Baltimore; for thirteen years assistant surgeon to the Presbyterian Eye, Ear and Throat Hospital; then for twelve years health warden of the city and later inspector for four years; died February 16.

William Arthur Wade, Murray, Utah; St. Louis College of Physicians and Surgeons, 1888; aged 73; for many years a pharmacist and a member of the first state board of pharmacy; an examiner for the first medical board of Utah; formerly local surgeon to the San Pedro, Los Angeles, and Salt Lake and Rio Grande Western railroads; at Payson, Utah; died February 23.

George Turner Meacham, Taylorville, Ill.; Rush Medical College, 1893; aged 49; Lieutenant, M. R. C., U. S. Army, and discharged January 11, 1919; a member of the Illinois State Medical Society; formerly an alderman of Taylorville; died, March 8, from the effects of carbolic acid self-administered, it is believed, with suicidal intent, while despondent on account of ill health.

Silas Blaisdell Hull * Asst. Surg., Lieut., M. C., U. S. Navy, Brooklyn, N. Y.; Long Island College Hospital, Brooklyn, 1916; aged 24; who served for two years in foreign waters in the mine sweeping service; a member of the Association of Military Surgeons of the United States; physician for the National Bank of Commerce, Brooklyn; died, March 6, from encephalitis.

Albert F. Koetter * St. Louis; Missouri Medical College, St. Louis, 1892; aged 48; a member of the American Otolological Society; instructor in otology in Washington University and chief of the ear clinic of O'Fallon Dispensary; aurist to the Evangelical Deaconess Hospital; once president of the St. Louis Medical Society; died in Barnes Hospital, St. Louis, February 28.

Samuel Richard Guthrie, Franklin, Ky.; Vanderbilt University, Nashville, Tenn., 1913; aged 32; a member of the Kentucky State Medical Association; Captain M. R. C., U. S. Army, with service in the British Army from 1917 until the close of the World War; and discharged July 9, 1919; died at the home of his parents in Franklin, February 21, from pneumonia.

Flavel Shurtleff, Pekin, Ill.; Rush Medical College, 1865; aged 78; assistant surgeon of U. S. Volunteers during the Civil War; from 1877 to 1891 county clerk of Tazewell; for twenty years one of the publishers of the *Pekin Times*; vice president of the Farmers National Bank for many years and a director in the Herget National Bank, Pekin; died February 24.

Henry A. Newbold, Philadelphia; University of Pennsylvania, Philadelphia, 1893; aged 74; demonstrator of practical pharmacy in the University of Pennsylvania; assistant in nervous diseases in the University and Polyclinic hospitals; a committing physician for the psychopathic ward of the Philadelphia Hospital; died, March 3, from arteriosclerosis.

Charles Philip Henry, Philadelphia; University of Pennsylvania, Philadelphia, 1882; aged 59; assistant surgeon, U. S. Navy, and retired Dec. 20, 1889, on account of incapacity resulting from an incident of service; a noted linguist; head of the Latin department of the Catholic High School for Boys, Philadelphia; died, February 26, from pneumonia.

Hosea Ballou Burnham, Manchester, N. H.; Vermont Medical College, Woodstock, 1853; aged 90; a member of the New Hampshire Medical Society; formerly consulting physician to the Elliot Hospital, Manchester, and physician to Rockingham County House of Correction and Insane Asylum; died February 29.

Alique C. Matchette, Bourbon, Ind.; Northwestern University Medical School, Chicago, 1863; aged 82; surgeon of United States Volunteers during the Civil War, and chief surgeon of the military division of West Tennessee; secretary of the local board of health for twenty-five years; died February 16.

William Alhanan Smith, Springfield, O.; Cincinnati College of Medicine and Surgery, 1877; Bellevue Hospital Medical College, 1883; aged 68; a member of the Ohio State Medical Association; a member of the medical staff of the Springfield City Hospital; died, February 25, from heart disease.

Charles Edgar Blanton, New Market, Ala.; Vanderbilt University, Nashville, Tenn., 1882; aged 66; a member of the Medical Association of the State of Alabama; for several terms president of the Madison County Medical Society; died, February 20, from pneumonia.

Walter H. Parcels, Lewistown, Pa.; Medical College of Ohio, Cincinnati, 1873; aged 71; a member of the Medical Society of the State of Pennsylvania; a veteran of the Civil War; twice representative in the state legislature from Mifflin County; died February 2.

Albert D. Marks, La Mesa, Calif.; College of Physicians and Surgeons, Baltimore, 1885; aged 69; died, February 18, from the effects of a stab wound of the heart believed to have been self-inflicted with suicidal intent, while despondent on account of ill health.

William Allen Deas, Richmond, Va.; Medical College of Virginia, Richmond, 1879; aged 85; a member of the Medical Society of Virginia; formerly coroner of Henrico County, and physician at the Soldiers' Home; died in Williamsburg, Va., February 17.

Henry Leo Keyes Carey, New York City; Eclectic Medical College of the City of New York, 1894; Bellevue Hospital Medical College, 1897; aged 52; for fifteen years examining physician for tuberculosis in the Department of Charities; died March 6.

Willis W. Munson, Otisco, N. Y.; George Washington University, Washington, D. C., 1869; aged 79; a veteran of the Civil War; once president of the Onondaga County Medical Society; died in the Soldiers' Home, Bath, N. Y., February 28.

H. A. Moorman, Owenboro, Ky.; Louisville, Ky., Medical College, 1889; aged 76; a member of the Kentucky State Medical Association; for many years president of the Sacramento, Ky., Deposit Bank; died, February 24, from heart disease.

John W. Dulaney, Greenwood, Miss.; Tulane University, New Orleans, 1873; aged 73; a member of the Mississippi State Medical Association; died in St. Joseph's Hospital, Memphis, Tenn., March 2, after an operation for appendicitis.

Thomas Elwood Taylor * Denver; University of Michigan, Ann Arbor, 1879; aged 64; professor of obstetrics in the University of Colorado, Denver and Boulder, and later emeritus professor; died, February 2, from cerebral hemorrhage.

Leonard Frederick Schmauss * Alexandria, Ind.; Rush Medical College, 1897; aged 52; while driving his automobile across the Big Four tracks, two miles north of Alexandria, February 27, was struck by a train and instantly killed.

Samuel B. Flynt, Meridian, Miss.; Memphis, Tenn., Hospital Medical College, 1898; aged 57; died in a hospital at El Paso, Tex., February 14, from injuries received in an automobile accident near Newman, N. M.

John M. Fitzgerald * Clarion, Pa.; Western Reserve University, Cleveland, 1872; aged 71; once treasurer of the Clarion County Medical Society; died, February 27, from pneumonia following influenza.

Samuel Hunt, Jr. * Knoxville, Tenn.; Vanderbilt University, Nashville, Tenn., 1914; aged 29; Lieutenant M. R. C., U. S. Army, with service in France, and discharged May 4, 1919; died February 23.

Charles John McGuire, Altura, Minn.; University of Illinois, Chicago, 1902; First Lieutenant, M. R. C., U. S. Army, and discharged August 9, 1919; died, February 25, from cerebral hemorrhage.

Elisha H. Coombs, Morgantown, W. Va.; Hahnemann Medical College, Philadelphia, 1860; aged 84; president of the Monongahela Valley Bank, Morgantown; died about February 19.

William Brown Maney, Nashville, Tenn.; University of Nashville, Tenn., 1856; aged 85; chief surgeon of the First Tennessee Infantry, C. S. A., during the Civil War; died February 22.

John B. Draper, Oswego, Kan.; Rush Medical College, 1868; aged 77; formerly surgeon of the State Soldiers' Home, Fort Dodge; a veteran of the Civil War; died about February 25.

Thomas R. Plumer, Farmington, Ill.; (license, years of practice, Illinois, 1873); a member of the Illinois State Medical Society; a practitioner for sixty years; died about March 1.

Charles Edwin Bleakley, Detroit; Michigan College of Medicine and Surgery, Detroit, 1889; aged 63; also a graduate of the Ontario College of Pharmacy; died February 25.

Edward Remson Seasongood * Naper, Neb.; John A. Creighton Medical College, Omaha, 1910; aged 34; also a graduate in pharmacy; died, February 27, from pneumonia.

John Campbell Brewer, Lytton Springs, Tex.; Medical College of Georgia, Augusta, 1871; aged 72; a member of the State Medical Association of Texas; died February 3.

James F. Harris * Ogden, Ill.; Kentucky School of Medicine, Louisville, 1877; aged 67; a member of the Illinois State Medical Society; died, February 28, from influenza.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

MORE MISBRANDED DRUGS

Boericke & Runyon Tablets.—In September, 1917, Edward A. Runyon, New York City, who traded as Boericke & Runyon, shipped some tablets in interstate commerce that were adulterated and misbranded. "Santonin and Calomel Tablets," labeled as containing $\frac{1}{2}$ grain each of santonin and calomel to each tablet, were found, in fact, to have approximately only 0.402 grain santonin and 0.352 grain calomel to each tablet. "Acetanilid and Quinine Compound Tablets," labeled as containing $\frac{1}{4}$ grain caffeine citrate and 1 grain of quinin sulphate in each tablet, were found to contain approximately only 0.201 grain caffeine citrate and 0.842 grain quinin sulphate. Some 5 grain "Aspirin Tablets" were found on examination to contain no aspirin at all but to be composed of salicylic acid, milk sugar and talc. "Kali Hydroid Tablets" (potassium iodid) declared to have 1 grain of potassium iodid to each tablet, were found to have in fact only 0.566 grain potassium iodid. Some $\frac{1}{4}$ grain "Morphin Sulphate Tablets" contained in fact approximately only 0.071 grain morphin sulphate to each tablet. Runyon pleaded guilty to the charges of adulteration and misbranding and was fined \$25.—[*Notice of Judgment No. 6551; issued Feb. 21, 1920.*]

Sulferro-Sol.—Sulferro-Sol, fourteen cases of which were alleged to have been shipped in February, 1918, by the Sulferro-Sol Co., Inc., Birmingham, Ala., was declared misbranded by the federal officials. It was charged that the claims made for the product "falsely and fraudulently represented it as a remedy for pellagra, dyspepsia, indigestion, anemia, chronic abscesses, and all forms of stomach, kidney, skin, blood and nervous troubles; whereas, in truth and in fact it was not." No claimant appearing for the property, the court ordered it condemned and forfeited and instructed that the stuff itself should be destroyed while the empty containers should be sold at public auction.—[*Notice of Judgment No. 6564; issued Feb. 21, 1920.*]

Santal Pepsin Capsules.—Augustus R. Kaylor and Clara J. Sadd, Bellefontaine, Ohio, who did business under the trade name Santal Pepsin Co., shipped in interstate commerce a quantity of "Santal Pepsin Capsules" in May, 1917. When analyzed by the Bureau of Chemistry these were found to consist of soft gelatin capsules containing about 10 grains of a mixture of santal oil, methyl salicylate, salol and a tablet containing pepsin. It was falsely and fraudulently claimed on the trade packages that the preparation was a specific for all kidney and bladder troubles, gonorrhea, gleet, inflammation of the ovaries, rheumatism, Bright's disease and a number of other conditions. In November, 1918, Kaylor and Sadd pleaded guilty and were fined \$175 and costs.—[*Notice of Judgment No. 6569; issued Feb. 21, 1920.*]

Principles of Hygiene.—One of the main principles of hygiene is to bring about a consistent common-sense observance by individuals and communities of cleanly methods of living to prevent the erupted matter from the bodies of infected persons from being conveyed to and becoming "dangerous dirt" in the bodies of other persons. Another important matter is the establishment and maintenance of conditions in respect to air, water, food, exercise, and sleep, which tend to fortify individuals with vigorous health and the power to overcome invasion of the body by "dangerous dirt."—L. L. Lumsden, "Rural Hygiene," *Public Health Rep.*, Nov. 7, 1919.

Correspondence

THE NATIONAL FORMULARY, USEFUL DRUGS, AND THE COMING REVISION OF THE PHARMACOPEIA

By the federal Food and Drugs Act and by state acts, two books are made the official or legal standards for drugs and their preparations, namely, the Pharmacopeia and the National Formulary. The Pharmacopeia does not standardize all drugs and preparations. On the contrary, it is highly selective; and while at each decennial revision it has admitted some new and approved remedies and their preparations, it has also sought to eliminate from its pages those remedies that have failed to combine both worth and extensive employment. In the last revision it gained much by eliminating many of those preparations, formerly so much in vogue, that had a shotgun make-up or were combinations which forbade simplicity in prescribing.

The National Formulary, revised and issued by the American Pharmaceutical Association, is in a sense supplementary to the Pharmacopeia, for its drugs and preparations are those which have been discarded from the Pharmacopeia in the different revisions, together with some other compound preparations which are frequently prescribed or are extensively called for by the laity. In a large measure it is a book of convenience for the pharmacist, enabling him to furnish preparations of definite strength and uniformity for those physicians who still prescribe the discarded formulas of the Pharmacopeia or stick to the old-fashioned galenicals. In addition, since it can be depended on to some extent as a standardizer for the discards of the pharmacopeial revision, it gives added freedom to the pharmacopeial revisers in their design to exclude preparations not fully approved, even though much used.

As these two books are the legal or official standards, their drugs and preparations can be obtained of definite strength and uniformity of manufacture throughout the United States. It follows, then, that their preparations should be the ones preferred in prescribing. But who would care to memorize the Pharmacopeia or the National Formulary? It would be a waste of time and energy, for nearly all the matter in both books relates to tests for purity and identity, and the technique of manufacture. This is material for the supply houses and the pharmacists, to enable them to select drugs of high quality, and to manufacture preparations of uniformity. All that the physician needs out of the official books is the names of the substances standardized, and the strengths of approved preparations. He does not require either the National Formulary or the Pharmacopeia. But he does require some book that from the vast amount of matter embodied in the Pharmacopeia and the National Formulary furnishes him with the names of such drugs and the strengths of such preparations as he may need for intelligent prescribing. He also requires a book so constituted that it will permit of frequent revision, and thus include remedies recently introduced to the profession and not yet adopted by the Pharmacopeia.

Such a book is "Useful Drugs," published by the Council on Pharmacy and Chemistry of the American Medical Association. It is of pocket size, gives the names and strengths of approved official preparations, and includes some drugs and preparations of recent introduction that are not official. In addition, it gives brief summaries of the actions and uses of all the drugs of which it treats, with their properties, incompatibles and doses. It is essentially a selective compendium and should, for the present at least, be the practitioner's Pharmacopeia. Without in any way intending to speak disparagingly of the Pharmacopeia or the National Formulary, I believe that "Useful Drugs" is the best book for the physician. But it has no control over standards and must depend for these almost wholly on the Pharmacopeia. Hence a proper revision of the Pharmacopeia is of the greatest interest and importance to us.

The Pharmacopeial Revision Convention meets in Washington in May of this year. It is made up of delegates

from the medical and pharmaceutical colleges, the state and national medical and pharmaceutical societies, and certain other selected societies, and the Army, Navy and Public Health services. Its function is to determine the principles which shall govern the next revision of the Pharmacopeia, and to elect officers and a Committee of Revision. As we physicians are the ones to prescribe the drugs and preparations of the Pharmacopeia, it is beyond cavil our function to exert ourselves and make certain that the principles adopted shall suit us, and that the revision committee elected shall be in sympathy with our desires. To accomplish this the first thing to do is to see to it that every medical college and every medical society selects interested delegates to the convention, and pledges them to attend the convention. If this is done we need not fear for the result.

I would suggest that when we meet in the convention, we should stand together for two demands: 1. That it is the right of the prescribers of drugs as represented by the medical delegates to the convention to say what drugs and what preparations are to be considered by the Committee of Revision. This done, we can safely leave the methods of manufacture and the tests and other matters to the pharmaceutical, chemical and other delegates. 2. That every means be employed to abolish dilatory methods in the revision, so that we shall not again, as in the last revision, have the amazing lapse of more than six years between the meeting of the convention and the establishment of the revised book as the official Pharmacopeia.

For details of changes to be urged I would suggest:

1. That glandular drugs and their pure principles be introduced as far as possible, e. g., epinephrin, corpus luteum; ovarian extract, etc.

2. That the name of each alkaloidal salt be accompanied by a statement of its percentage of pure alkaloid. For example, quinin tannate contains only 30 to 35 per cent. of quinin, and morphin sulphate contains only three-fourths its weight of morphin.

3. That drugs and preparations which do not combine decided worth with use be dropped. A tentative list of such is: acetum scillae, acidum stearicum, althaea, aqua creosoti, arnica, calcium bromid, calcium hypophosphite, chondrus, cimicifuga, emulum asafetidae, eriodictyon, gnaia, guarana, humulus, liquor iodi compositus, manna, matricaria, mel, mel depuratum, mel rosae, mezereum, mistura glycyrrhizae composita, oleatum hydrargyri, pepo, petroselinum, pyrethrum, sabal, sinapis alba, stillingia, syrupus hypophosphitum, taraxacum, trituratio elaterini (not elaterinum itself; elaterin can be prescribed without an official dilution quite as well as any of the potent alkaloids), trochiscus sodii bicarbonatis, unguentum hydrargyri nitratis, xanthoxylum, zinci sulphocarbolas, zincum, and all oleoresins except that of aspidium. Substances of pharmaceutical value only, such as stearic acid, althaea and honey, should not cumber the body of the book. It is to be borne in mind that most of the substances dropped will still find a place for standardization in the National Formulary, and will therefore continue to be available in standardized form for those who wish them. But they should not receive the recognition of a highly scientific and exclusive book such as we desire our Pharmacopeia to be.

4. That all fluidextracts with dose below 5 minims be dropped, and if necessary replaced by a 10 per cent. tincture. It is agreed that many fluidextracts, because of their concentration, cannot be made to hold all the active principles of the drug from which they are made, and that they are subject to material changes of strength from precipitation or evaporation. The requirement of assayed strength does not change these facts. It has been shown repeatedly that the average fluidextract of digitalis is not ten times as strong as the tincture, as it should be, but perhaps only about three times as strong! With potent drugs this is a serious matter.

5. That newly introduced chemical substances of proved worth be included. It is a crying shame that our Pharmacopeia does not yet recognize solution of epinephrin (adrenalin) chlorid, argyrol, acetylsalicylic acid, arsphenamin, etc. Even though they are patented preparations they should be

given some recognition, the Pharmacopeia stating that they are patented and giving the time of expiration of the patent.

6. That the genitive of all titles be appended. How many of us, for example, in prescribing milk of magnesia, know that in a prescription the official preparation should be written "Magenitis magnesiae" and not "Magnae magnesiae"?

7. That whisky and brandy be restored. With our new prohibition laws these medicinal liquids will be as precious as potent tinctures, and will need standards if they never did before.

I make these suggestions for the medical delegates, and urge that we take our next month's pharmacopeial convention seriously. For the sake of the best medical practice, all medical colleges, all state medical associations, and any other medical body which has the privilege of sending delegates to next year's pharmacopeial convention should appoint these without delay and see to it that they attend the convention with some understanding of their responsibilities.

W. A. BASTEDO, M.D., New York.

Fifth Vice President, U. S. Pharmacopeial
Convention of 1920; Assistant Professor
of Clinical Medicine, Columbia University
College of Physicians and Surgeons.

STOLEN SURGICAL INSTRUMENTS

To the Editor:—Two bags of instruments, dressings, etc., and a small mahogany clock were stolen from my office three weeks ago. I have recovered one of the bags with many instruments, but they are not mine. It seems that somebody is gathering these for resale. I would suggest that if second-hand instruments are offered to any physician for sale, he should appear to be too busy to pass judgment at the time, regardless of the story told, but ask the person to return in an hour or two, and, retaining the instruments, in the meantime call an officer: all this, of course, to be modified according to circumstances. Perhaps a central reporting place for lost and found instruments would discourage theft. The owner of the instruments that I have may obtain them by calling at my office.

WILLARD MANFORD, M.D., Detroit.

LEPROSY IN THE AGED

To the Editor:—I have before me the issue of THE JOURNAL for Nov. 15, 1919. In the second column on page 1547 appears: "DR. H. R. CARTER, Baltimore: There is good reason to believe that leprosy is *rarely* or *never* communicated to elderly persons. In taking care of lepers I would suggest that elderly nurses be employed, as the risk of such people contracting the disease is *absolutely nil*."

The italics are mine. Probably most workers among lepers would agree with a general statement to the effect that elderly persons are less likely to become infected with the disease than are young persons. Perhaps the speaker only wished to make his idea stick in the minds of his hearers by making it overstrong; but I want to protest against the use of the words that I have italicized, as being likely to mislead our confrères in America.

Having seen the usual number of cases of leprosy that come to medical missionaries here, during thirty years' residence in Foochow, where leprosy is a very common disease, I cannot refrain from saying that such experience quite contradicts the very positive statements made above. Just recently an old Bible woman that has been working among lepers here for years, a woman who was very careful about her contacts with them, who was unusually cleanly in every way, has developed the disease. Her contact with the lepers could not have been as intimate as that of persons caring for such cases, for that was not her duty at all, and the years that she had been engaged in the work might have seemed to justify a statement almost as strong as the one to which I object; but there is no doubt that the woman is now infected. Other cases have come to my attention in the past, but this is the latest one and answers, as well as any

number, to emphasize the point that I make. Elderly persons may and do contract leprosy, though they are probably less likely to do so than younger persons.

H. N. KINNEAR, M.D., Foochow, China.

INTERNATIONAL COMMITTEE OF THE RED CROSS OF GENEVA, AND THE LEAGUE OF RED CROSS SOCIETIES

To the Editor:—My attention has been called to an article in THE JOURNAL, Jan. 31, 1920, p. 334, concerning the coming meeting of the General Council of the League of Red Cross Societies. A confusion exists in the mind of the writer of this article between the International Committee of the Red Cross of Geneva and the League of Red Cross Societies, which also has its headquarters in Geneva. These two institutions are entirely distinct, and there is no official connection between them. The International Committee of the Red Cross of Geneva is composed of seventeen citizens of Switzerland, and has been in existence since the founding of the Red Cross by Henri Dunant in 1863. During the war the International Committee of the Red Cross of Geneva served as intermediary for the exchange of prisoners. The League of Red Cross Societies is constituted by thirty national Red Cross Societies, as follows: Argentina, Australia, Belgium, Brazil, Canada, China, Cuba, Czechoslovakia, Denmark, France, Great Britain, Greece, Holland, India, Italy, Japan, New Zealand, Norway, Peru, Poland, Portugal, Roumania, Serbia, South Africa, Spain, Sweden, Switzerland, the United States, Uruguay and Venezuela.

WILLIAM R. HEREFORD, Geneva, Switzerland.

Director, Department of Publicity and Publication, League of Red Cross Societies.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

BOOKS AND PERIODICALS ON OTORHINOLARYNGOLOGY

To the Editor:—1. I intend specializing in the ear, nose and throat. What textbooks do you advise me to get on these subjects?

2. Is there an atlas of anatomy, pathology or surgery (of one, two or all three) published of the ear, nose and throat?

3. Who publishes "The Nose and Throat in Medical History," by Jonathan Wright?

4. Is there a book published containing the biographies of the great men in medicine or "Who's Who" in medicine?

5. What journals on otology, rhinology and laryngology would you advise me to subscribe to?

6. Who publishes the *British Journal of Otology, Rhinology and Laryngology*?

M. L. SOWERS, M.D., Allston, Mass.

ANSWER.—

1. Packard: Nose, Throat and Ear, Philadelphia, J. B. Lippincott Company, \$4.

Ballenger: Ear, Nose and Throat, Philadelphia, Lea & Febiger, \$5.50.

Kyle: Nose and Throat, Philadelphia, W. B. Saunders, \$5.

2. Kricg: Atlas of Diseases of Nose, New York, Paul B. Hoeber, \$12.

3. Wright: Nose and Throat in Medical History, St. Louis, L. S. Matthews, \$2.

Wright: History of Laryngology, Philadelphia, Lea & Febiger, \$4.

4. Garrison: History of Medicine, Philadelphia, W. B. Saunders Company, \$7.50.

Medical men are also included in the ordinary editions of "Who's Who."

5. The following journals are published in America:

Annals of Otology, Rhinology and Laryngology, Jones H. Parker, Mermod-Jaccard Bldg., St. Louis, \$6.

Laryngoscope, 3858 Westminster Place, St. Louis, \$6.

6. The *British Journal of Otology, Rhinology and Laryngology*, published by Adlard & Son and West Newman, Ltd., Bartholomew Close, London, E. C. N., £1.

Good Health.—Euphonious definitions of good health are numerous. Clear conceptions of good health are rare. It is easy to define; difficult to conceive.—W. S. Rankin, *Tr. Assn. Life Ins. Presidents*, 1919.

RHODE ISLAND: Providence, April 1-2. Sec., Dr. Byron U. Richards, State House, Providence.

WEST VIRGINIA: Charleston, April 13. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

New York May and June Examination

Mr. Herbert J. Hamilton, assistant, professional examinations, New York State Board of Medical Examiners, reports the written examinations held at New York City, Buffalo, Syracuse and Albany, May 21-24 and June 25-28, 1919. The examination covered 8 subjects and included 10 questions. An average of 75 per cent. was required to pass. Of the 384 candidates examined, 306, including 2 osteopaths, passed, and 78, including 1 osteopath, failed. The following colleges were represented:

College	PASSED	Year Grad.	Number Licensed
Leland Stanford Junior University	(1917)		1
George Washington University	(1916)		1
Rush Medical College	(1915)		1
University of Illinois	(1919)		1

Maine November Examination

Dr. Frank W. Searle, secretary of the Maine State Board of Registration in Medicine, reports the written examination held at Portland, Nov. 12-13, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 11 candidates examined, 9 passed and 2 failed. Three candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Medical School of Maine	(1883)	(1883)	82
Johns Hopkins University	(1900)	(1900)	82
Tufts College Medical School	(1919)	(1919)	80
Columbia University	(1913)	(1913)	86
University and Bellevue Hospital Medical College	(1910)	(1910)	84
Jefferson Medical College	(1914)	(1914)	89
University of Vermont	(1917)	(1917)	79
Laval University	(1919)	(1919)	78
McGill University	(1917)	(1917)	79

Book Notices

LES LÉSIONS DES NERFS: TRAITEMENT ET RESTAURATION. Par Mme. Athanassio-Benisty, Ancien Interne des Hôpitaux de Paris. Paper. Price, 7 francs net. Pp. 156, with illustrations. Paris: Masson et Cie, 1919.

In this small volume, Mme. Athanassio-Benisty presents much that was included in the second volume of her work on peripheral nerves as it appeared in the *Horizon Collection* and in the English translation in the *Medical War Manuals*. The subject-matter has been brought up to date, particularly with reference to the surgical treatment, the prognosis, medicomilitary decisions, and the important work of Dustin on intraneural localization. Each of the chapters constitutes a comprehensive and adequate review of the author's wide experience and the recent literature. The description of the signs of restoration of function in peripheral nerve lesions is exhaustively treated, and at this time will be found of great value to American neurologists and surgeons who are following the results obtained in the treatment of injuries of peripheral nerves in the late war. The observations are in accord with the experience of the reviewer, but do not seem to be entirely in accord with the theories of Head, Rivers and others relative to the return of sensation, although an attempt is made to fit the clinical findings to their theory. In this volume, as in the preceding publications, there is an exhaustive description of orthopedic apparatus, which is preeminently applicable at this time in our treatment of lesions of the peripheral nerves.

THE URETHROSCOPE IN THE DIAGNOSIS AND TREATMENT OF URETHRITIS. By Major N. P. L. Lumb, O.B.E., R.A.M.C. Cloth. Price, \$2.75. Pp. 51, with 40 illustrations. New York: William Wood and Company, 1919.

The author asserts that he derived the incentive for writing this booklet from the fact that in no work that has come to his notice has an attempt been made to show the effect of treatment on the lesions of urethritis which can be observed with the urethroscope. Authors of special textbooks on this subject will regret that their work has been thus unnoticed. The illustrations, though somewhat schematic and considerably magnifying the natural size of the field of view, come up to a fair standard. Inflammatory granulomas, so often observed, and known as maintaining obstinate gonorrheal inflammation, have not found a place in this treatise. Many urologists will be surprised at the author's assertion that it is usually possible to clear up a prostatic abscess by massage and general treatment. Inaccuracies in the text, as "the vascular striation is seen to best advantage in this region and consequently any abrasion of the surface . . . leads to considerable bleeding" (page 7), or, as in the discussion of gonorrheal epididymitis, "when the testicle has settled down" (page 47), should not occur in a treatise that pretends to be the last word in systematic treatment of gonorrhea.

EXPERIMENTAL PHARMACOLOGY. By Hugh McGuigan, Ph.D., M.D., Professor of Pharmacology in the University of Illinois, College of Medicine. Cloth. Price, \$2.75. Pp. 251 with 63 illustrations. Philadelphia: Lea & Febiger, 1919.

A period of relative stagnation in the production of works on experimental pharmacology has been replaced by one of relative productivity. Within the last few years a number of commendable texts have either been thoroughly revised or written anew. Most of them have been overwhelmingly personal, so that it is gratifying to find one in which "no claim to originality is made." Rather an effort has been made to include standard exercises. To a certain extent this book is a synopsis of drug action on various anatomic systems. It is sufficiently brief so that the student is not robbed of the opportunity to display his originality. It is a fairly satisfactory guide in his work. One regrets that the proof-reading was not done with greater care. For example, the careful student may be mystified by the "apparatus for anesthesia by intracranial insufflation" (p. 33).

KOMPENDIUM DER TOPISCHEN GEHIRN UND RÜCKENMARKSDIAGNOSTIK. Kurzgefasste Anleitung zur klinischen Lokalisation der Erkrankungen und Verletzungen der Nervenzentren. Robert Bing, a.o. Professor an der Universität Basel. Vierte, neu durchgesehene Auflage. Mit 97 zum Teil mehrfarbigen Abbildungen.

The author states that this edition is practically a replica of the third, such a short time having elapsed between the two. The book remains, then, what it was: first, an excellent outline of the essentials of the structural anatomy and applied physiology of the central nervous system; secondly, a rather full summary of localizing diagnosis of lesions of cord, brain stem, cerebrum and cerebellum. Fully to cover the subject and at the same time make every part of the text clear to the tyro is impossible. The author's attempt is quite as successful as one could expect. The internist and surgeon generally will find what they are looking for, and the neurologist may here quickly pick up some strand dropped from memory's thread. The illustrations are well chosen and easily understood, and the index is adequate.

Medicolegal

Validity of Law Relative to Disfigurement

(*New York Cent. R. Co. v. Bianc* (U. S.), 40 Sup. Ct. R. 44)

The Supreme Court of the United States holds constitutional the provision of the workmen's compensation act of the state of New York that, in case of an injury resulting in serious facial or head disfigurement, the state industrial commission may in its discretion make such award or compensation as it may deem proper and equitable in view of the nature of the disfigurement, but not to exceed \$3,500. The court says that the sole contention here was that this provision deprived the employer of property without due process of law, in contravention of the fourteenth amendment of the constitution of the United States. The argument was that an award for disfigurement, made wholly independent of the claimant's inability to work, was not based on impairment of earning power; that only such impairment could justify imposing on an employer without fault compulsory payment by way of compensation to an injured workman; and hence that the disfigurement clause was not a reasonable exercise of the police power, but was arbitrary and oppressive. But even were impairment of earning power the sole justification for imposing compulsory payment of workmen's compensation on the employer in such cases, it would be sufficient answer to the present contention to say that a serious disfigurement of the face or head reasonably may be regarded as having a direct relation to the injured person's earning power, irrespective of its effect on his mere capacity for work. Under ordinary conditions of life, a serious and unnatural disfigurement of the face or head very probably may have a harmful effect on the ability of the injured person to obtain or retain employment. Laying aside exceptional cases, such a disfigurement may render one repulsive or offensive to the sight, displeasing, or at least less pleasing, to employer, to fellow employees, and to patrons or customers. But this court cannot concede that impairment of earning power is the sole ground on which compulsory compensation to injured workmen legitimately may be based, although unquestionably it is a rational basis. In this court's opinion, the "due process of law" clause of the fourteenth amendment does not require the states to base compulsory compensation solely on loss of earning power. The court sees no constitutional reason why a state may not, in ascertaining the amount of such compensation in particular cases, take into consideration any substantial physical impairment attributable to the injury, whether it immediately affects earning capacity or not. Whether an award for such disfigurement should be made in combination with or independent of the compensation allowed for the mere inability to work is a matter of detail for the state to determine. The same is true of the question whether the compensation should be paid in a single sum, or in instalments.

Indemnification Against Liability for Malpractice

(*Schamps v. Fidelity & Casualty Co. of New York* (U. S.), 259 Fed. R. 55)

The United States Circuit Court of Appeals, Sixth Circuit, says that a surgeon carried with the defendant company a policy of so-called liability insurance, limited to \$5,000. An action for malpractice was brought against him by one Rainsford. The company assumed the defense of the suit. Rainsford obtained judgment for \$10,000. The company, with the consent of the surgeon, decided not to prosecute any proceeding for review. Thereupon the surgeon filed a voluntary petition and was adjudged a bankrupt. He scheduled this judgment as his only debt, and showed assets of some \$400. The trustee in bankruptcy, after providing for expenses, paid a 2 per cent. dividend on this claim—the only one proved—and thereupon brought this action to recover from the company the \$5,000 named in the policy. The company contended that it was liable only for what the surgeon or his trustee had paid to Rainsford, namely, \$200, and the trial court took that view.

That portion of the policy which directly imposed liability read as follows: "[The company] does hereby agree: (1) To indemnify . . . assured against loss from liability imposed by law on assured for damages on account of bodily injuries or death suffered by any person or persons in consequence of any malpractice, error or mistake of the assured. . . . (2) To defend, in the name and on behalf of the assured, any suit brought against the assured, etc." Later clauses specifically provided (7) that the company would continue the defense of any such suit "until a final decision is rendered in the assured's favor, or until the case has been appealed to the highest court to which an appeal can be taken, or until the suit has been settled with the written consent of the assured," and (9) that the assured should not "voluntarily assume any liability nor incur any expense, . . . nor, except at his own cost, settle any claim, nor . . . interfere in any negotiations or legal proceedings conducted by the company on account of any claim."

On the merits, the controlling question was this: Did the company indemnify against any part of the Rainsford judgment which the surgeon or his estate had not paid? The question, in somewhat analogous cases, has been considered to be whether the indemnity was against liability or was only against ultimate loss, and there is supposed to be a sharp conflict of authority between the cases which classify such policies in one or the other category, although, when the court comes to consider the peculiar language of this policy, it does not find any embarrassing conflict. In policies of this nature, the distinction was early recognized between insurance against liability and indemnity against damages. In view of this distinction, it became common to insert in such policies the provision known as the "no action" clause, which provided that, for example: "No action shall lie against the company as respects any loss under this policy, unless it shall be brought by the assured himself to reimburse him for loss actually sustained and paid by him in satisfaction of a judgment after a trial of the issue."

Under such "no action" policy, it was held, in Massachusetts, that the plain and express language of the policy must be given effect, and that the duty to indemnify did not arise until the judgment was paid, and this conclusion has been quite generally adopted in cases involving "no action" policies. But in the present instance the company omitted the "no action" clause from the policy. The court does not find any substantial inconsistency between clause 1 and the later clauses mentioned; but it does think it clear that, as the word "loss" is used in clause 1 it is ambiguous, and it holds that when the parties, in clause 1, referred to a "loss from liability," they intended that kind of a loss which, in ordinary nomenclature and thought, comes into existence when the liability of the assured becomes irretrievably fixed, so that the plaintiff, who was the trustee in bankruptcy of the surgeon's estate, was entitled to prosecute this action at law; in accordance with which view the judgment of the court below is reversed, and the case remanded for a new trial.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Joint Annual Conference of the Council on Medical Education of the American Medical Association with the Association of American Medical Colleges and the Federation of State Medical Boards of the United States, held in Chicago, March 1-3, 1920

(Continued from p. 761)

Report of Committee on Medical Education and Pedagogics of the Association of American Medical Colleges

DR. W. S. CARTER, Chairman, Galveston, Texas: It did not seem practicable to prepare reports on all the subjects of the medical curriculum at this time, and hence these were limited to the fundamental medical sciences which are taught by laboratory methods during the first and second years, with the exception of public health and preventive medicine, which is usually taught in the years devoted to clinical subjects. The preparation of these reports is in no way a duplication of the work done by the committee of one hundred appointed by the Council on Medical Education in 1909. The purpose of the reports to be presented is not to standardize, but to consider the methods of teaching the subjects that occupy the preclinical years.

Teaching of Gross Human Anatomy

DRS. C. M. JACKSON, WILLIAM KEILLER and C. R. BARDEEN: The chief factor in teaching gross human anatomy is the professor. His most essential natural endowments are executive capacity and ability for constructive scientific research. His special training, in addition to a thorough grounding in gross and microscopic anatomy, embryology and physiology, should embrace the broader aspects of biology and anthropology, on the one hand, and pathology and clinical physiology, on the other hand. To keep up an adequate supply of teachers of this type it will be necessary to have salaries for those who make good on a par with those offered full-time clinical teachers. The education of the medical student in gross human anatomy has to do with work in (a) technic; (b) terminology and topography; (c) comprehension, and (d) initiative:

Education in technic should include (1) preparation of material for study, (2) methods of study, and (3) expression of observations and ideas. The chief training in technic of preparation for students of gross human anatomy is train-

ing in dissection. As a rule, this is well taught in our schools at present. The training in methods of study is fairly well done so far as the student is taught to make use of text-book and guide while dissecting. The student, should be encouraged to go beyond this and to make use of reference books, special preparations, roentgenograms and similar facilities. It is more important for a student to learn to know how to seek light on an obscure question of structure than it is to commit to a memory necessarily imperfect a vast amount of detail well recorded in every textbook. Training in technic of expression is more neglected than it should be in our anatomic departments if we consider its importance from the standpoint of practice of scientific clinical medicine.

By training in terminology and topography we mean acquiring the use of anatomic terms in association with a visualization of the structures to which these terms refer. It is now generally recognized that in order to aid this association of ideas, anatomic terms should be learned in the dissecting room. The old fashioned didactic lecture has practically disappeared in teaching gross anatomy.

One of the most difficult tasks in teaching gross human anatomy is to lead the student to comprehend the subject. For the average medical student the comprehension of structure from the standpoint of function seems most important. For this purpose the living model, and the fluoroscope and roentgenogram are of great help.

Gross human anatomy offers an unusual opportunity for training in initiative. If granted considerable freedom, the student may waste some good anatomic material; but he has not the opportunity to injure physically either himself or other people or valuable property he would have if granted the same freedom in most laboratories or in the clinic. Since initiative is so important a quality for a physician, it seems clear that advantage should be taken of the opportunity for encouraging initiative in gross human anatomy.

Teaching of Histology and Embryology

DR. F. C. WAITE, Cleveland: By means of questionnaires, the subcommittee collected the opinions of teachers in forty-four of the fifty-nine medical schools then in membership in the Association of American Medical Colleges. The following preliminary conclusions are reached after a digestion of these opinions:

TERMINOLOGY

The word embryology is a sufficient title for the courses in embryology given in the medical schools, without any designation as to whether it is vertebrate, mammalian, human, etc. The course on the gross and microscopic anatomy of the nervous system and sense organs is best designated by the term neuro-anatomy, since the term neurology is so largely used to designate courses in diseases of the nervous system. The part of the course on the finer anatomy of the organs exclusive of the nervous system and sense organs is best designated by the term organology. The part of the course on the fundamental tissues is best designated as histology, and this term should be restricted to this field and not used as a general term to include organology also. If the term is not so restricted, then the term general histology should be applied to that part of the course on the fundamental tissues. In the course in histology and organology, histologic technic should not be a required part; but the laboratory should furnish loan collections to the student to be returned at the end of the course.

HISTOLOGY AND ORGANOLGY

The course in histology and organology, exclusive of any histologic technic, requires at least 180 scheduled hours, of which from 35 to 40 per cent. should be devoted to histology and from 60 to 65 per cent. to organology. Of the scheduled time, approximately 25 per cent. should be given to didactic work and 75 per cent. to laboratory work. For efficient teaching, the number of instructors must be such that in the laboratory there are not more than from twenty-two to twenty-four students to each instructor; and if the best results are to be obtained, there should not be more than from

sixteen to eighteen students to each instructor in the laboratory. The course in histology and organology should be given in moderate concentration extending over from sixteen to eighteen weeks.

EMBRYOLOGY

The course in embryology should be a separate course given either parallel with or following organology. The course should occupy approximately 100 hours of scheduled time. From 30 to 40 per cent. of this time should be devoted to the development of forms below mammals, and the balance to mammalian embryology. Embryology lends itself to greater concentration of schedule than do histology and embryology, and the course should be covered in from eight to twelve weeks.

The courses in histology, organology and embryology should be given in the first year, beginning either at the beginning of the year or sometime in the first half year. The shortness of time available and the varied wishes of the clinical instructors make it impossible to make the first year courses in this field courses in applied organology. They must primarily prepare for physiology and pathology (for which this work should be prerequisite), and therefore be on a broad basis rather than planned to prepare separately for each of the several clinical subjects and specialties.

RESEARCH

There apparently is little time that is available for elective courses in this field. Research in this field cannot be expected from the ordinary undergraduate medical student. Only students who are exceptional in preparation and ability and who can give additional time should be expected to do research.

Teaching of Neuro-Anatomy

DR. IRVING HARDESTY, New Orleans: The name neuro-anatomy is accepted for the course by 56 per cent. of the colleges answering the questionnaire, while 24 per cent. specify the term neurology. Others suggest excellent but more cumbersome terms. Doubtless, nearly all prefer neurology in that it is shorter and carries the more suitable meaning—knowledge or discussion of the nerves or nervous system—while neuro-anatomy carries the untrue inference that the subject is wholly anatomy. The minimum time necessary should be given as from 120 to 132 hours at least. Neuro-anatomy requires more concentrated and consecutive effort on the part of the student and instructor than any other division of anatomy. It deals with one continuous functional apparatus, knowledge of which must be added to day by day, with as little break in effort and as little diversion by other courses as possible. We urge that concentration of hours is very profitable for the student learning it.

From the very nature of what the course should be, it is obvious that the courses in histology and embryology should be required as prerequisite to entering the course in neuro-anatomy. The dissection of the entire body should be completed before neuro-anatomy is begun, certainly the head, neck and thorax. A supplementary review course in neuro-anatomy is advisable in the later years of the curriculum, introductory to the work in nervous and mental diseases. Cooperation in teaching among the staffs of neuro-anatomy, physiology, pathology and the staff of nervous and mental diseases is necessary. Anatomic names used should be as short as possible and each carry the proper functional significance in its meaning. The tracing of nerve paths is by far the most important object of the course.

Teaching of Physiology

DR. E. P. LYON, Minneapolis: A teacher of physiology should have (1) thorough training in biology, chemistry, mathematics and physics; (2) several years' study in a physiologic laboratory; presided over by a productive and stimulating professor, and (3) appreciation of the aims and problems of practical medicine. For the latter purpose, clinical training is desirable, but not indispensable. No amount of clinical training can take the place of the first and second elements of a physiologist's education. It does not matter what degree the physiologist attaches to his name,

provided he has brains and proper training. The head of a department of physiology, in addition to the training outlined above, should be an inspiring leader to his staff and students. The quality of scientific imagination is essential in this connection. Select a man with this education and these qualities, gives him freedom and security of tenure. Do not "teach" him to death. Give him an adequate salary. Supply a well trained staff. Don't forget that his leading subordinates should be strong men and should have good salaries, not a third or half, but three quarters or 90 per cent. that of the chief. Supply such salaries, not only because they are deserved, but because from this group of assistants come the future leaders. We must have a "school" or physiology and some future for its students, or they will leave pure science, as they are now doing.

As to methods of teaching, freedom must be permitted. The lecture is valuable for those who possess good power of exposition. The laboratory course is important and needs most careful and skilful teaching. It should not be left to subordinates. The laboratory work should be quantitative so far as possible. Problems for mathematical solution are valuable.

The course should include a judicious selection of frog, turtle, mammalian and human experiments. Demonstrations should be used to a considerable extent. Students should assist and be required to work up quantitative data on demonstrations. The laboratory and demonstration work must be used to form the background for a large amount of necessary didactic work. The field is too large for a student actually to see every part of it; but unless a basis of observation is provided, visualization from description cannot be even approximately correct. This thought should always determine the relation of didactic to laboratory work. Any device, such as theses, required reading and special problems that will send students to the library should be used. The entire course in physiology should be developed from the standpoint of "principles" rather than that of "technic" or that of "useful information." Principles are just the underlying facts. They are not theoretical abstractions or unproved hypotheses. Physiology teachers can and should introduce useful special facts and useful methods into their teaching; but unless they give their students a thorough knowledge of the facts of universal application, i. e., principles, they will not furnish a fitting background for modern clinical training.

DISCUSSION

DR. BURTON D. MEYERS, Bloomington, Ind.: The time has come to establish a course in neuro-anatomy, but it must depend on the equipment which the department has for teaching the subject. You cannot teach neuro-anatomy without having a complete series of sections from the cervical nerve up beyond the anterior commissure to be used in the projection apparatus. Then, one can give the course in neuro-anatomy in from eighty-five to 105 hours.

DR. H. GIDEON WELLS, Chicago: The committee on teaching anatomy made a mistake in selecting its sources of information. It should have sent the questionnaires to pathologists in order to get a heartfelt constructive criticism, because the pathologist is the man who has to handle the work of the anatomist. He acts as a buffer between the anatomist and the clinician. A large proportion of pathologists feel that an undue proportion of the time assigned to them in the curriculum, if not most of it, is spent in remedying the deficiencies in instruction in anatomy.

DR. J. P. JOBLING, New York: Students come to us with an excellent knowledge of the relation which one tissue bears to another, with the vascular and nerve supply; but if you take a fresh liver at necropsy, make a section of it throughout, and separate the lobule, students want to know what it looks like. They know what it is histologically; they do not visualize what fresh tissue looks like. My suggestion is that in the course on anatomy we should show students a fresh liver, make sections, show the appearance of the normal organ, and compare it with the abnormal. It is not only important from the standpoint of the pathologist, but also from that of the surgeon. When he operates he wants to

know what the tissues are, yet the anatomist does not give him any information from his pickled organ of what such a tissue should look like.

DR. JAMES EWING, New York: I agree with Dr. Wells that the committee made a fundamental error in the selection of its sources for information. It should have referred the questionnaire to the students and got their reaction. I am a teacher of laboratory subjects and am aware of the weaknesses of technic that students fall into. We become enamored of our methods of putting knowledge into the heads of students, and sometimes we forget what the object of our work is.

DR. W. F. R. PHILLIPS, Charleston, S. C.: As a teacher of anatomy, the only method I know of is that indicated by Vesalius when he used his own hands in teaching anatomy. I know of no other way to teach anatomy than to put the student before the subject and say, "There it is: go to it."

DR. IRVING S. CUTTER, Omaha: I have asked some practitioners and students where they learned the most anatomy and learned it best, and I was astonished at the answer, namely, at the postmortem table.

Teaching of Biologic Chemistry

DR. OTTO FOLIN, Boston: Closely associated with the problem of the necessary entrance requirements in chemistry is the question as to the amount of time that should be allowed for the teaching of physiologic chemistry in the medical school. Physiology and physiologic chemistry should have about the same time, and one fourth of a college year should be given to each of these two subjects. The time allotted to a laboratory subject like biochemistry is meaningless unless individual space and equipment for uninterrupted individual work are provided. It is also necessary that there should be in the laboratory at least 10 per cent. of unoccupied desk space available for miscellaneous uses for extra reagents, polariscopes, colorimeters, scales, etc.

The course in physiologic chemistry should consist of from seventy-five to eighty lectures and conferences (except so far as some of the lecture periods are used for one-hour written examinations), and an equal number of laboratory periods, two and one-half hours each (except so far as some of these are replaced by practical examinations). The first two weeks in the laboratory are needed for the preparation of standard solutions involving the use of the balance and for learning volumetric analysis. The lectures during this time must be partly instructions concerning the laboratory technic, but should deal mainly with the chemistry of solutions, the theory and practical use of indicators, and such topics as osmosis, reversible reactions, and the law of mass action. The work in volumetric analysis leads directly to the subject of quantitative nitrogen determinations, and the students can at once apply and fix their newly acquired experience by working on pure nitrogenous compounds. The lectures and reading at this time can advantageously cover the field of catalysis leading up to a general consideration of the field of enzymes. This work covers about three weeks, or from fifty-five to sixty hours, and trains the student as no other kind of work can train him in precision and attention to details.

The elementary first course in physiologic chemistry, coming as it generally does during the second half of the first year or first half of the second year, is not a course in pathologic chemistry, yet it includes the principles and methods on which the later applications to clinical materials are based. The student should not examine stomach contents, yet he studies pepsin and peptones, he learns to differentiate between hydrochloric acid and lactic acid, and he acquires some familiarity with the pigments of bile. He need never see a urine representing diabetes or nephritis, yet if given such a urine at the end of his course in physiologic chemistry he should be able to make a better chemical examination than he would four years later, when he is engaged as an intern in a hospital.

The examinations in biochemistry should be partly practical, partly written. These examinations should be numerous enough to permit a partial classification of the students by the time the course is half over. The practical examina-

tions can advantageously consist, in part, of problems which the student solves when he gets ready, at a time chosen by himself; but, in part, they must consist of general examination sessions. Four such general examinations (besides the final) are a large enough number. These may be thus distributed: The first, volumetric analysis (including nitrogen determinations), the differentiation between strong and weak acids, and the use of different indicators. Second, the reactions of fats and carbohydrates, including sugar titrations. Third, identification of protein materials and milk constituents, including quantitative milk analysis. Fourth, urine analysis and other topics. It is not possible to take more than one-half the class at a time for these practical examinations. They will therefore occupy either eight laboratory periods, or four lecture plus laboratory periods.

There is urgent need for some constructive recommendations as to how the great and growing demand for well trained and productive biochemists by medical schools and hospitals may be met.

DISCUSSION

DR. A. P. MATTHEWS, Cincinnati: The need of medical institutions in this country is research. The future of medical education lies in research. All the problems of instruction will solve themselves as soon as we realize that the development of the research spirit is at the bottom of all good education.

DR. FRANK BILLINGS, Chicago: The practitioner or clinician who does his work most efficiently is found to have been well grounded in the fundamentals in medicine. We have in this country an enormous number of physicians practicing medicine. The greater number of them graduated before we had made much, if any, advance in medical education. They do not think in terms of anatomy, physiology, pathology, physiologic chemistry or normal physiology. They think only of a patient and of an opportunity to prescribe some drug. I do not think we have time enough in two years in which to teach the fundamentals of medicine properly, and we are embarrassed when we speak of a curriculum of both the fundamental and clinical branches to find enough time to teach both, so that the product is the best that can be turned out.

The Larger Function of State University Medical Schools

DR. WALTER A. JESSUP, Iowa City: Our experience in Iowa leads to these conclusions: First, in view of the great rapidity with which the demands on our hospital and university staffs have grown, it is important that any state, in attempting to provide this type of service, should make liberal provision in space and staff for adequate service not only to indigents, but also to the ever growing number of pay patients. Second, future plans should include ample provision for the vigorous prosecution of medical research. Otherwise the teaching staff may easily be overwhelmed with routine, with a consequent slump in growth. Furthermore, the unusual clinical demands serve as a constant challenge to the student of medicine. Third, since the success of the work is absolutely dependent on skill and devotion of the staff, it is essential that many adjustments in the conditions of teaching must be made. The problem of full time clinical teaching becomes more acute.

Other departments of technical education have had to meet the same situation. Indeed, in the field of agricultural education a very large part of the function has been the providing of service for the public. So much is this true that it would be hard at the present moment to conceive of a college of agriculture without its elaborate organization in the direction of special agricultural service to the state. Within the next few years we may expect in many state universities just such close coordination in the problems of the training of physicians, furthering research that will contribute to the knowledge of the field and extending health service to the public. In the degree that the colleges of medicine of the state universities are alert to these new demands and effective in their responses will they become real leaders in this present movement looking toward the highest type of physical and mental efficiency.

Full-Time Teachers in Clinical Departments

DR. WILLIAM DARRACH, New York: In regard to clinical teachers, there exists considerable ambiguity in the conception of the full-time or university basis, as is evidenced by the widely divergent plans of organization now in force or planned in the various schools of the country. In several medical schools the departments of medicine, surgery and pediatrics are being reorganized on what is spoken of as the "full-time" or "university" basis. It is being widely accepted that such an arrangement is necessary for the best type of teaching, for the most successful clinical investigation and for the most skilful care of the sick. The essential principle of this arrangement is that the dominating group of men in the main clinical departments must be free to concentrate their energies on their university and hospital work. A year ago I was frankly opposed to the university basis being applied to the clinical departments of a medical school. But as a member of a committee which has been earnestly seeking light on medical school organization, I have become completely converted to the principle.

There are two main factors which tend to interfere with this freedom, no matter how sincere the intentions of the men may be. These factors are insufficient assistants and the distractions of private practice. By providing the full-time men with sufficient assistants, professional, clerical, technical and menial, he may relieve himself of such unnecessary details as he desires. He must also be protected from the demands of private practice. The main purpose is to obtain a more truly university type of clinical teacher. The full-time plan is a means to this end—a method by which it may be obtained.

The various so-called full-time plans may be thus summarized: (1) no private practice and no outside employment; (2) private practice at the discretion of the clinician, but no fee paid for such service; (3) as in Plan 2, except that the fee is paid to the university; (4) private practice for fees allowed in such limited amounts that it does not interfere with the thorough, efficient and sincere fulfilment of his academic duties; (5) unlimited private practice within the hospital.

The specific plan which we have proposed and hope to put into effect is as follows: The fundamental principle on which these departments shall be reorganized is that the control of each main clinical department shall be vested in a director, associated with a differentiated group of men who are devoting all their time to the school and hospital, that they may build up and maintain a department in which the best intensive clinical investigation and scientific research may be carried on with the teaching of students and the care of the sick. Of more importance than salary for either type of man is the proper arrangement of his work, so that he shall be freed from unessential details and useless waste of time. In the end the opportunity to carry on teaching and research under wholesome surroundings is the most effective force for bringing into the medical school men of ability and ideals. The head of the department with these associates should form an administrative board, which could relieve him of as much of the administrative details of the hospital and of the teaching as he chose. Unless he is so relieved and protected from the innumerable distractions of departmental matters he will prove sterile as a producer and will soon cease to be the inspiring and stimulating leader so necessary in a department of this kind. These men should have as much time for constructive thought and productive leisure as the head of a large industrial concern. By such a combination and coordination the department would become a well-rounded unit, which should result in great progress along all three lines—research, teaching and care of the sick.

(To be continued)

Reporting Communicable Diseases.—Whenever a physician fails to report a communicable disease, the entire community is unnecessarily exposed to the contagion. Such failure may be attributed to sheer negligence, to wilful disregard of the obligations imposed by statute, or to a mistake in diagnosis.—*Connecticut Health Bull.*, October, 1919.

Epidemic Encephalitis and Catatonic Symptoms.—Five cases are cited by Bond. He says that his aims in presenting these cases are to inquire into the difficulties in the descriptions of postures and motor symptoms, and to suggest the plausibility of cerebral disturbance as a basis for "catatonic" episodes. In three of the cases, episodic disturbances of the brain were located by cranial nerve involvement; in another case, by this and necropsy. Most important is the fact brought out by these cases that very mild and transient, but definite, symptoms are usually missed in excited, seclusive or indifferent patients. In one case, strabismus went unrecognized at home; another patient, because she had no psychosis, was able to give information which would have been lost in a person less clear. It is interesting that these patients began to improve after dental attention, one after thyroid therapy and one immediately after lumbar puncture.

Histopathologic Findings in Dementia Praecox.—The twelve cases studied by Rawlings gave quite uniform pathologic findings which are due neither to arteriosclerosis, senility nor a long continued grave toxic process. This pathologic process is essentially a chronic one, resulting in an atrophy of the nerve cell body and its nucleus, a disappearance of its stainable substance, an attenuation, with partial fragmentation, of its neurofibrils and an atrophy with distortion of its protoplasmic prolongations; the process terminating in either extreme pyknotic atrophy in which the shrunken cell and its prolongations are seen covered with incrustations or in a fragmentation of the nerve cell to the extent that it is either a shadowy outline or an atrophic nucleus surrounded simply by a fragmented rim of pale granular protoplasm. While no special effort is made by Rawlings to trace the disease process, a general impression is obtained from the study of the various types of cells in all strata that the initial process is one of moderate swelling of both cell body and nucleus followed by a gradual breaking down of the normal nuclear chromatin structure and later, by an atrophy and fragmentation of the neurofibrils with subsequent granular degeneration and irregular clumping of the Nissl granules. The final stage terminates in one of two conditions according to the degree of the vicious influences or the original resistance of the cell, namely, moderate atrophy, followed by more or less acute fragmentation and extreme pyknotic atrophy.

Larceny and Emotional Repression.—The three cases reported by Spaulding represent attempts to compensate for emotional repression, which has been associated with a distressing mental conflict. In the first case, there was an internal fermentation, which bubbled over in an antisocial way when the patient, because of unusual strain in her environment that made her past more oppressive than usual, was unable to obtain an emotional outlet and a feeling of compensation through her religion. That she chose the outlet she did instead of others apparently resulted from the

fact that this particular act typified to her the worst thing she could do and represented an attempt to win back-favor and effect a reconciliation. The patient's married life was marred by her difficulty in adjusting herself to marital conditions and her inability to obtain children by adoption. In the third case, emotions had been aroused at an early age in a way in which there was such a strong association to shame that everything even remotely connected with the sexual sphere had in consequence been repressed. The energy that had been repressed as a result of the conflict had expressed itself asocially in several ways, one of which was stealing. The outlets that she chose seemed to furnish her in some way with what is called an illusion of compensation.

Drainage as an Antimalaria Measure.—This paper was abstracted in THE JOURNAL, Nov. 22, 1919, p. 163.

Bacteriology in Food Control.—In summing up the future outlook for the application of bacteriology in food control, it seems probable to Jordon that increasing emphasis will be laid on bacterial methods as an aid to the interpretation of the sanitary inspection of foodstuffs and as a guide to satisfactory sanitary procedure. Continued laboratory investigation of the two best known instances of so-called "food poisoning" traceable to primary bacterial food contamination, botulism and paratyphoid meat poisoning, seems urgently called for since both are intimately connected with the vital problems of food conservation. Finally, the nature and sanitary significance of the products generated by bacteria, particularly the so-called saprophytic bacteria, in foodstuffs affords a practically untouched field for investigation.

*Solar Keratoses and Cutaneous Cancer. J. N. McCoy, Vincennes, Ind.—p. 175.
*Dermatologic Misnomers. M. Scholtz, Los Angeles.—p. 182.

Burning Tongue.—Eleven cases of burning tongue are reported by Engman. None of these patients showed any lesions of the tongue, except enlarged papillae from constant feeling for the sensation against the teeth, and all of them were in an almost terror stricken condition for fear of carcinoma of the tongue. Engman's course of procedure in the treatment of such patients has been to be frank with them by stating that several such instances have been observed, and that the condition is no doubt due to a subconscious fixing of the mind on the anterior portion of the tongue, suggested by some instance which they have not consciously observed—possibly a remark from some one as to cancer of

the tongue, or hearing or reading of such cases. It is somewhat similar to the "idée fixée" of French writers. However, one possible cause of this sensation in the anterior portion of the tongue may be inflammation of the lingual tonsil on either side, as was pointed out by Sluder.

Ulcerating Granuloma of Pudenda.—Goodman presents a review of the literature with a bibliography and some observations of the disease as seen in Porto Rico. Four cases of ulcerating granuloma of the pudenda are reported. In three of these cases, *Calimotobacterium granulomatis* was demonstrated for the first time in the United States or its dependencies. In one case, the spirochetal organism described by Wise was observed. Goodman emphasizes that the disease is not syphilis, although it may be associated with syphilitic lesions, or be present in a Wassermann positive syphilitic, free of syphilitic manifestations. Arsphenamin and mercury are ineffective in its treatment. Antimony and potassium tartrate was not given a sufficiently thorough trial to warrant any positive expression of its efficacy.

Erosive Vulvitis.—Three cases of this disease are reported by Driscoll. In each of the three cases, the Wassermann reaction was negative. There was no response to anti-syphilitic treatment, including arsphenamin treatment. In each case the characteristic spirochete and fusiform bacilli were isolated from the serum of the ulcers. Driscoll urges that any persistent erosive ulceration with negative Wassermann reaction should be regarded as suspicious, and some of the serum should be obtained for bacteriologic study. If the serum shows spirochetes and fusiform bacilli, the diagnosis is conclusive. The infection might, of course, be superimposed on other lesions of the genitals.

Solar Keratoses and Cutaneous Cancer.—From a study of the clinical histories of patients, McCoy is convinced that cancers of the mucocutaneous margin of the lip, or cancers commencing at that point, are in no way due to solar light. Further, the lips near the margin seem to be immune to the development of keratoses. He has never seen a keratosis at or near the lip margin. He also calls attention to the significant fact that while a large percentage of cutaneous cancers of keratotic origin are of the basal cell type, most cancers of the lip margin are of the cuboidal cell type. However, cutaneous cancer of covered parts is quite rare and, when found, is nearly always traceable to traumatism, while 37.7 per cent. of all cancers, both deep seated and superficial, have occurred on the face (exclusive of the lip margins), the hands and neck, parts exposed to solar light; and that they have attacked persons whose vocations or habits involved insolation to a considerable degree. McCoy agrees with Unna and others that insolation produces keratoses and that these are the most frequent of pre-cancerous lesions. Sixty-two per cent. of his patients were blondes, 7 per cent. were dark-skinned persons, and 31 per cent. were chatains, or persons having a skin only slightly pigmented. In as much as the keratosis is an admitted pre-cancerous lesion, McCoy advises that it should unfailingly be removed.

Dermatologic Misnomers.—Scholtz submits what he terms the most glaringly inconsistent and misleading misnomers of dermatologic nomenclature, such as erythema induratum, erythema nodulare and erythema multiforme, infectious eczematoid dermatitis, dermatitis repens, and other dermatitides, acne rosacea, sycosis vulgaris, etc., and pleads for their revision and correction.

Fat-Soluble Vitamin Content of Green Plant Tissues.—It appears that of the plant structures the leaves are generally richest in the fat-soluble vitamin; some roots are next in order, and last, at least of those investigated by Steenbock and Gross, are grains. Where certain yellow plant pigments occur there fat-soluble vitamins may be looked for. In harmony with this, it is seen that cabbage in the head, containing little pigment, is not to be compared in physiologic activity with the other leafy substances, and of these latter, lettuce, also somewhat etiolated, is the poorest.

Thermostability of Fat-Soluble Vitamin in Plant Materials.—A process of heat treatment, consisting of autoclaving for three hours at 15 pounds pressure, does not destroy any of the fat-soluble vitamin as found in yellow maize. Neither does this treatment cause any noticeable destruction of the vitamin in chard, carrots, sweet potatoes and squash. Experiments by Steenbock and Boutwell demonstrated that the fat-soluble vitamin as found in the plant kingdom in a grain, leaf and stem tissue, fleshy roots, and cucurbital vegetables is comparatively stable at a high temperature.

Hydrogen Ion Concentration of Human Duodenum.—The reaction of the duodenum between three and four hours after meals was usually found to fluctuate around the neutral point, but the extreme range on the acid side was greater than on the alkaline side, possibly due to the spurting of gastric contents into the duodenum.

Value of Hemoglobin Determination by Various Methods.—Various methods used for estimating hemoglobin percentage were compared by Rabsch. The Sahli hemoglobin method, when using the color tubes accompanying the instrument, gives very inaccurate results because of the decided variance in color density of the standard tubes, the result of fading. The Palmer method offers a very satisfactory means of hemoglobin determinations if the standard solutions are freshly prepared. Newcomer's method obviates many difficulties heretofore observed with other procedures, and gives good results with the glass 0.96 mm. in thickness, although the color is quite pale. A method is presented applying Palmer's procedure to Sahli's principle which has proved most satisfactory. It removes the difficulty encountered with Palmer's method, the lack of stability of color in the standard solutions. It has the advantage of an easier color match than that of red tint. The standards prepared have remained sufficiently unchanged for a period of eleven months to insure accurate hemoglobin determinations during this long period.

Digestibility of Certain Vegetable Fats.—The digestibility of several fats and oils has been studied by Holmes and Deuel. The digestibility coefficients obtained were: avocado fat, 87.9 per cent.; cohune oil, 99.1 per cent.; capuassu fat, 94.1 per cent.; hempseed oil, 98.5 per cent.; palm kernel oil, 98.0 per cent., and poppy seed oil, 96.3 per cent. The digestibility of the protein and carbohydrate of the entire ration was essentially the same as that in other experiments of a

similar nature, indicating that the fats exercised no unusual effect on the utilization of these constituents. These fats and oils, with the possible exception of capuassu fat, which caused slight disturbances, produced no abnormal physiologic effects, and may be regarded as satisfactory for food purposes. Cohune, hempseed, palm kernel and poppy seed oils especially are very highly utilized by the human body.

Method for Determination of Methemoglobin in Blood.—A colorimetric method for the determination of blood pigments is given by Stadie which is simple and rapid, and which, combined with a simultaneous determination of the hemoglobin by the gasometric method of Van Slyke, gives the methemoglobin content of the blood. The method depends on the fact that both hemoglobin and methemoglobin are changed quantitatively to cyanhemoglobin by dilute solutions of potassium cyanid.

Secretion of Gastric Juice.—Cohen claims that the total chlorids of gastric juice are secreted more or less constantly regardless of the free acidity of the gastric juice. They vary from 0.39 to 0.54 per cent. This may corroborate Pawlow's view that gastric juice is secreted with a constant acidity, and that variations are due to secondary neutralization. A large volume of juice secreted rapidly has a higher acidity than a smaller volume secreted slowly, other factors remaining constant (confirmatory of Pawlow).

- Focal Putrefactions and Their Bearing on Osteoarthritis and Other Diseases. S. L. McCurdy, Pittsburgh.—p. 92.

Arthritides and Focal Infection.—Some of the points emphasized by Gibney are: A focus of infection should be diligently sought for in every case of arthritis where tuberculosis, malignancy or trauma are not self-evident as causes or at least controlling factors. While the finding of a focus and the proper handling of the same may not be followed sooner or later by relief, it cannot be assumed that the infection is at an end. The arrest of the infection does not mean that the exudates in and around a joint will disappear unless orthopedic measures are employed to bring about resolution and restoration of function. The finding of one focus does not mean that this is the only focus bearing on the case. Many organs are exposed to bacteria of a pus producing nature, and that a careful study of these organs should be the rule.
